Prices on several well-known makes have been substantially reduced from the war-time levels and a better understanding of the limitations and use of such equipment is helping to establish a much more stable market for this important accessory.

Electric Control of Planer Table Movement

Small Pendent Push-Button Station for Setting-Up Period—Magnetic Contactors Mounted in Sheet Steel Enclosed Case—Armature Resistance in Rear—Speed Adjusted Without Opening Door

THE CONTROL of the planer by means of electricity is now being recognized as efficient practice. The following description of the Cutler-Hammer full-Magnetic planer controller should be of special interest to many readers.

"The drum type master is designed for operation from the planer table, the small pendent push-button station is used for operating during the setting-up period, the start and stop station is combined with a transfer switch for changing the control from the drum master to the pendent push-button station. It is also possible to provide a separate start and stop station for mounting on the opposite side of the planer from the combined station. A description of the full magnetic planer controller follows:

Main Controller

The main controller consists of a slate panel containing the magnetic contactors mounted in a sheet steel enclosing case with the armature resistance mounted in the rear and the field rheostats mounted on the inside of the door. On the panel are mounted two single-pole Cutler-Hammer circuit breakers with instantaneous trip coils and a manually-operated latch for tripping both breakers at the same time. Two field relays, a low-voltage release relay, a field knife switch with field discharge clips, four single-pole contactors with carbon contacts and mechanical interlocks for reversing, three lockout accelerating contactors and a spring-closed dynamic contactor. The field rheostats are mounted with the operating handle projecting through the door so that the speed can be adjusted without opening the door of the case. The starting resistance consists of cast iron grids mounted on rods and supported by the sides of the case. The protecting resistance consists of "S9" units mounted on an asbestos lumber board. The removable back makes it easy to inspect these resistances at any time.

The accessories consist of a drum type master for operation from the planer table, a pendent push-button station for operation during the setting-up period a "start" and "stop" station combined with a transfer switch for changing the control from the drum master to the pendent and also a separate "start" and "stop" station for mounting on the opposite side of the planer from the combined station.

Operation Features

For normal operation, the transfer button is moved to the drum position and the start button pressed. This closes the low-voltage release relay and one set of reverse contactors will close, depending upon the position of the drum master, if this is in the cut position. The cut reverse contactors will close and the motor will start with three steps of starting resistance in circuit. These will be cut out successively by the three accelerating contactors as the current comes down to normal. With the closing of the last accelerating contactor, the field relay opens up and puts the cut rheostat in series with the shunt field and the motor comes up to the speed for which the rheostat is set. At the end of the cut stroke, the drum master will be thrown over by the planer dog and the cut reverse contactor opened and the return reverse contactor immediately closed. This results in plugging the motor which is the fastest method of reversing it. At this time only the last two steps of accelerating resistance are in circuit. These are cut out by the last two accelerating contactors and the motor comes up to the speed for which the return rheostat is set. The reason that the two steps of resistance are used for plugging at the end of the cut stroke, while three are used at the end of the return stroke, is due to the fact that a voltage equal to twice normal is developed when the motor is plugged at the end of the cut stroke while three times normal voltage is obtained at the end of the return stroke, and the current must be held at a safe value in each case. This of course means a different value of resistance for the two strokes and is obtained in the manner described above. The equipment can be stopped at any time by pressing the "stop" button. This cuts the motor from the line and applies dynamic brake which quickly stops it. If the voltage fails at any time, the low-voltage relay releases at 70 per cent. of normal voltage and applies dynamic braking. This becomes an important function if the voltage should fail at the instant the table was about to reverse.

Setting Up a New Job

During the setting up of a new job, the pendent button is used. The control is transferred to this station by means of the transfer button. With this button the table can be operated in either direction by pressing the corresponding button, the motor running only so long as the button is held depressed. Dynamic brake is applied every time the button is released. Operation of the stop button opens the control relay which cuts resistance in series with the

Present Day Problems in Industrial Accounting

Questions Relating to Profit and Loss—Balance Sheet of Paramount Importance—Checking Inventories—Arriving at a Proper Working Basis—Value of Depreciation

BY STANLEY G. H. FITCH.

BROADLY SPEAKING, most accounting problems which we have to solve may be viewed from the standpoint of the balance-sheet. It may be argued that questions relating to the profit-and-loss statement should be separately grouped, but, after all, any transaction affecting the profits necessarily affects also some balance-sheet item, either an asset or a liability. The balance-sheet itself as to form and arrangement presents at once a problem of paramount importance, and in developing the subject we might naturally proceed to take up questions relating to the treatment of the several balance-sheet groups. Some may be wondering how such a treatment of the balance-sheet is going very far toward the discussion of problems in industrial accounting, that cost accounting, a highly important branch of industrial accounting involving the application of overhead expense to the cost of product, has a direct effect upon the subject of inventory valuation, which brings us back at once to the balance-sheet.

Form of Balance-sheet

Much has been written on the subject of a standard form of balance-sheet, but a casual reference to a few forms prepared by banks and bankers, which have been selected at random, discloses a striking lack of uniformity among those commonly used. In submitting a certified balance-sheet, should the accountant follow the form prescribed by the client's bank or by the broker who handles his paper, or should he adopt a form of his own, which in his judgment, owing to the peculiar circumstances of the case, sets forth clearly the client's financial condition, with particular emphasis upon certain outstanding features disclosed by the audit?

The author did not answer the question, but for the purpose of laying the foundation for discussion, mentioned some of the significant variations in three selected balance-sheet forms, designated for convenience as "A," "B", and C."

Current Assets

Balance-sheet "A" classifies as current assets, cash, notes and accounts receivable, inventories, quickly marketable securities and notes and accounts due from officers, stockholders and employees. Balance-sheets "B" and "C" include as current all of the foregoing assets except notes and accounts receivable from officers, stock-holders and employees. Such items in many instances may be slow in realization, but in the other cases they may be quick assets and, for the purpose of setting forth the assets available for meeting current liabilities, they should be included under those conditions as current assets.

Balance-sheets "A" and "B" make no provision for subdividing the asset items for notes, accounts receivable, merchandise or securities, so as to show what has been pledged as security for loans, while balance-sheet "C" assembles in a separate group all pledged current assets (notes and accounts receivable, acceptances, merchandise and securities). This arrangement shows at a glance the total amount of such assets pledged but, on the other hand, makes it impossible without recasting the balance-sheet to state the total amount of each asset, pledged and unpledged. Balance-sheet "A" very properly indicates that reserves for bad debts, discounts, allowances, etc., should be deducted from the asset, while balance-sheets "B" and "C" provide for reserves upon the liability side of the balance-sheet. Inasmuch as the purpose of the balance-sheet is to show the net amount likely to be realized from the liquidation of any current asset, the former method is to be preferred.

Balance-sheet "A" does not provide, however, for a separate classification of notes and accounts due from controlled or subsidiary concerns, and, while such a subdivision is made on balance-sheets "B" and "C," the items are not classified as current assets. It may be pertinent to remark, however, that a scrutiny of the balance-sheets of the subsidiaries might disclose that the balances due the parent company were offset almost wholly by current accounts and notes receivable from customers, so that in reality the balances due from the subsidiaries on the parent company's books actually represent assets more "current" from the standpoint of quick realization in cash than inventories classified as current assets on the balance-sheet forms in question.

Current Liabilities

All three balance-sheets ("A," "B" and "C") include as current liabilities notes payable, accounts payable and accrued items (taxes, interest, etc.), while on balance-sheets "B" and "C" are set forth as separate items dividends declared and payable. Balance-sheets "A" and "B" clearly indicate the separation of notes payable as unsecured and secured respectively, but the amounts are grouped so as to show the total notes payable, while balance-sheet "C" shows notes payable, secured by notes receivable, accounts receivable, trade acceptances, merchandise and securities as a separate group. This arrangement is open to the same criticism as applied to the relative pledged assets: that it does not disclose at first glance the aggregate of an important liability, viz., notes payable, including both unsecured and secured notes.

It is worthy of note also that in balance-sheets "B" and "C," notes and accounts payable to controlled or subsidiary concerns are included in current liabilities, while, as previously mentioned, notes and accounts receivable of similar concerns are excluded from current assets. If such accounts and notes payable by the parent company to the subsidiaries represent deferred liabilities, they can properly be excluded from the current liability classification.

Fixed Assets

While the three balance-sheets under discussion differ as to degree of detail in stating the fixed assets, there are two important variations calling for comment: first, balance-sheet "A" provides for the deduction from the fixed assets of the reserve for depreciation, while balance-sheets "B" and "C" indicate no such application of depreciation reserves in reduction of the respective assets but show the reserves on the liability side of the balance-sheet. The former method is to be preferred in that it shows at once the net book value of the fixed assets and precludes the inclusion of the reserves with surplus. Secondly, on balance-sheet "A" goodwill is deducted from the total of capital stock and surplus in stating net worth, while on balance-sheets "B" and "C" goodwill is shown in the usual way on the asset side of the balance-sheet. In some circumstances, where goodwill is carried at an inflated value, the former method would no doubt be justifiable, but in other cases, where goodwill has a clearly demonstrated value, the virtual writing off of the goodwill value would be far from a correct procedure.

Valuation of Inventories

The valuation of the inventory at the balance-sheet date determines to a great extent the profit or loss for the prior fiscal period and the financial condition at the close. Consequently, the inventory is rightly subject to close scrutiny on the part of those concerned in granting credit on the basis of the balance-sheet submitted.

Some of the questions usually asked are these: Was a physical inventory taken or does the inventory reported represent a book balance with or without supporting perpetual inventory records? If a physical inventory was

taken, did the auditor assist in or supervise the actual counting, weighing and listing of the stock? How was the inventory valued, i.e., at cost or at cost or market whichever was lower? How were values and market values ascertained and does the company operate a cost system? Were the calculations and footings carefully checked to obviate clerical errors, which, while unintentional, have the same effect as deliberate falsification of the inventory? And, finally, to what extent did the auditor verify the work of the client's force, and how far is he responsible for the value reported? The manner in which the inventory is shown on the balance-sheet, in conjunction with the auditor's certificate thereto, should be a satisfactory answer to the last question.

Cost Accounts in Relation to Inventories

An allowance for overhead should be included and opinion is fairly unanimous that overhead so included should be limited to that relating to manufacturing or production, as distinct from selling and general expenses. But in times of depression, overhead costs soar, while the increase in direct costs is relatively small. In the case of merchandise manufactured under such conditions, should it be inventoried at actual cost, which means virtually the absorption of losses directly attributable to idle capacity?

Aside from the accounting aspect of the case, what is the effect on the balance-sheet offered for credit purposes? Balance-sheets of borrowers are now perhaps more than ever before subject to searching scrutiny by bankers and credit-men, and in a great number of cases their attention is focused upon the inventory as the key to the borrower's financial condition. The familiar phrase describing the valuation of the inventory as "cost or market whichever is lower" may possess special significance. What does "cost" mean, especially with reference to finished product manufactured when production is far below normal? Does "cost" mean that actual overhead charges have been loaded upon the merchandise, thereby inflating the book value by inclusion of unearned overhead which should have been charged to profit-and-loss? Is it truthful to say "merchandise is valued at cost," when in effect the inventory includes deferred charges to profit-and-loss, which should have been written off in the period just closed, instead of being carried forward as a burden to be taken up in the ensuing periods?

Obviously the only fair cost to use in the valuation of an inventory is a normal or standard cost. If that basis has been used, supported by details drawn from the cost records, the borrower will be in a strong position to maintain his credit with his banker, while if the other basis has been used, i.e., inflated values arising from excessive overhead in costs, the credit-man's mind is at once charged with doubt as to the soundness of the borrower's balance-sheet.

In the operation of a highly developed cost system, which recognizes interest on capital as an element of cost, it is customary to allocate to each manufacturing department its proportion of such interest and to include that interest in the departmental overhead which is distributed to production centres or to individual machines. Such overhead (including interest) is absorbed in the cost of the product which passes through the several departments. Consequently, if we take as an example a finished machine, the product of a textile machinery plant, the cost is represented by the aggregate of the costs of a multiplicity of parts, made in different departments, including a proportion of the charges for interest on capital allotted to the respective departments but merged with other overhead charges.

If the interest charge is allowed to remain in the cost of that machine for inventory purposes, we have an inflated value arising from the inclusion of an unrealized profit. This is generally recognized by the proponents as well as the opponents of interest as an element of cost. In arriving at a proper inventory basis there remains, then, only one further step, and that is to eliminate the interest from the cost of the finished product. That sounds very simple, but actually it is practically impossible because the identity of the charges has been lost in the distribution of the overhead, and the process can be reversed only with extreme difficulty.

Purchase Commitments for Future Delivery

Recently many losses entailed in deflating inventory values were recognized and taken into account in preparing annual balance-sheets, but other similar losses arising from purchase-contract commitments for future delivery could only be approximated. During the period of deflation in commodity prices, through which we have just passed, great stress was rightly laid upon the borrower's purchase commitments and their probable effect upon his ability to meet his obligations or perhaps even his prospects of continuing in business. In order to obtain supplies of materials it was necessary to make purchase contracts, and in a period of falling prices losses were in many cases unavoidable. Bankers justly required full information bearing upon the borrower's liabilities of that nature. With the return to a period of stable prices, losses on commitments become less a cause for anxiety. We as accountants face the problem as to what extent we shall inquire into and report upon purchase commitments which are made in the ordinary course of business. One banker expressed the opinion that he was not interested in contracts made under such conditions; but others held opposite views.

Obligations of the Auditor

The public accountant must always be on the alert for clauses in bond indentures and capital-stock certificates, which delegate to him definite responsibilities. Certified statements are frequently required under such conditions, but a study of the documents may develop the need for a legal interpretation of the meaning of a clause which may be construed in more than one way. Whose advice shall the auditor take in order to meet his responsibilities intelligently and properly?

In one case recently under consideration the definition of "quick assets" required careful interpretation. In another case the basis of the inventory valuation, as set forth in the indenture, could be construed in more than one way. In a third case the auditor was charged with the responsibility of determining what constituted "adequate" depreciation before certifying the profits available for dividends, and in a lean year he was forced to take issue with the corporation officers. The foregoing illustrations demonstrate the need that the auditor inform himself as to what his responsibilities are before he affixes his signature to a certificate.

The ideal conditions leading up to an unqualified certificate cannot always be realized. But the practice of issuing a statement which is merely a condensed copy of a trial balance, with a certificate stating in effect that the balances agree with the books and have not been otherwise verified, should in my opinion be discouraged, not because the accountant says he has done anything which he has not done, but because of the failure of many bankers and business men to read the certificate and to understand its significance. They see merely a balance-sheet statement over the auditor's signature and assume that it is an audited statement.

Not long ago, a banker expressed himself as unable to understand why a certain corporation had gone into the hands of a receiver within three months after issuing a satisfactory statement of condition over an auditor's certificate. Upon inquiry as to the form of certificate, the statement was produced which showed a "certificate" to the effect that the statement was only a condensed copy of the trial balance and that no audit whatever had been made. The fact was that the banker either did not read the certificate or did not realize its significance.

A problem which is only indirectly related to the balance-sheet is the conflict bewteen established accounting procedure and federal tax regulations. Many of us have frequently been asked by clients for counsel as to the advisability of adjusting their books to conform to the results of audits of tax returns according to federal tax regulations. Charges for depreciation and repairs have been a constant cause of dispute between the taxpayer and the treasury department, resulting in disallowances of such charges in many cases. Should the asset account, surplus account and depreciation reserve account then be adjusted upon the books? Obviously the book-keeping would be simplified for future years by maintaining only one set of accounts, without the

Drilling Operations in Automobile Axles

Jigs and Fixtures Used in Front and Rear—Bringing Axles Into Proper Alignment—Machining the Housings—Adapting Tools to the Required Work—Following Each Step Through to Completion

By ROBERT MAWSON

SOME of the machining methods followed in the manufacture of axles for automobiles of different types are shown and described in this article.

The first illustration, Fig. 1, shows the drilling of the rear axle sub-assembly. The axle housing, spring support and brake arm have been assembled in previous operations, the face of the housing having also been faced in a lathe. This assembled set of units is then placed in the jig being located by means of a turned register which fits into a machined recess in the flange A, and a pin B, which fits into a reamed hole in the brake arm. When the piece is in position as shown 8-29/64 inch holes are drilled.

The half tone, Fig. 2, shows the jig used when machining the differential housing. This element has been turned and faced, also the center hole bored and reamed in previous operations. The piece is then placed on the plug A and forced into the jig with the nut and washer as shown. Four 47/64 inch holes are then drilled in the piece, the jig being indexed around to the several positions by means of the index pin B which fits into bushings in the revolving part of the tool.

Under the jig C may be seen a latch handle which also fits into notches, the inner end of the latch being machined for that purpose, the duty of this attachment is to assist the man operating the tool to find the indexed positions more readily than if he depended solely on the indexing pin. After the four holes have been drilled, they are reamed out to ¾ inch, the tool being guided in bushings similar to the drilling operation.

Drilling the Front Axle

The illustration, Fig. 3, shows the special machine set up and jig used when drilling the front axle. It will be seen that this tool is made in the form of a base A which is fastened securely to the machine table. At each end of this base are movable members, as B, which are made with vee blocks C used to bring the ends of the axle into the correct alignment. This is performed by means of the hand wheel D which operates a screw with left and right hand threads, so that as the hand wheel is turned the sliding members are either brought nearer together or forced out according to the motion imparted to the hand wheel. The hand wheel, therefore, brings the axle into the proper alignment and by reason of the vee blocks also holds it in that position. Knurled head screws are then tightened against the forging to assist in holding it and also force it down onto the lower seat of the sliding fixture members. The spring seat bolt drilling jigs F are separate jigs held to the main base of the fixture and may be adjusted if desired to obtain any spring distance desired within the range of the fixture. The spring seat drills are driven by means of multiple heads held and driven with the spindles G. All the holes are machined together, in other words four spindles are in operation together and as can be readily seen such a set up is a great time saver and can be truly called a production operation. With this fixture two holes are drilled, one at each end, 1-21/32 inch diameter. The guide bushing is then changed and these holes reamed to 1-11/16 inch. In each spring pad four 17/32 inch holes are drilled, and it may be added that this set up not only machines axles quickly but what is of more importance of an interchangeable nature.

Drilling Gear Housing

The next illustration, Fig. 4, shows the jig used when drilling the pinion gear housing. This casting has been faced and a register machined on the same surface in a previous operation.

The piece is then placed into the jig and located by means of a recess which is made to suit the turned register on the housing face. It will be noticed that this part is made with bosses through which it is desired to drill the holes both for appearance and also to obtain the necessary strength as a holding medium for the bolts.

This is done in rather a novel manner on this jig. On the face of the tool at A are made a series of marks and the

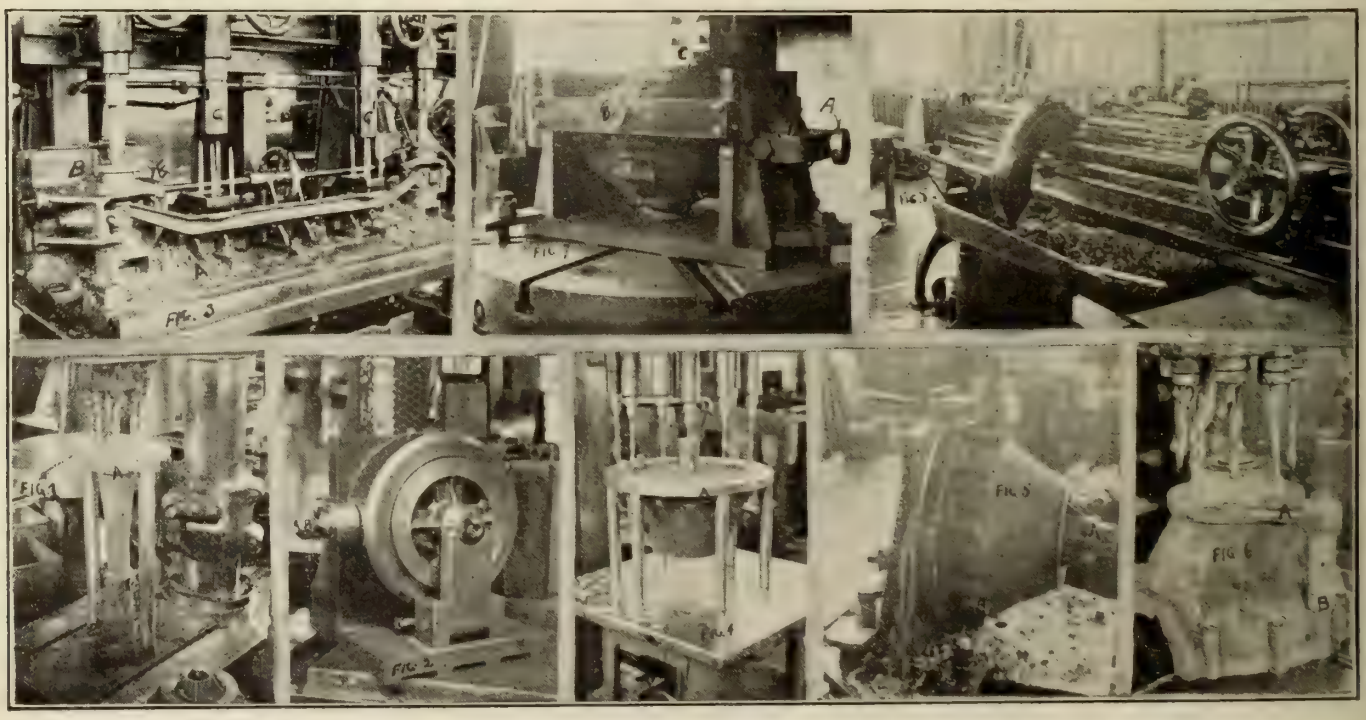

Fig. 1.—Drilling rear axle sub-assembly. Fig. 2.—Machining differential housing. Fig. 3.—Drilling front axle. Fig. 4.—Drilling pinion gear housing. Fig. 5.—Drilling holes in side. Fig. 6.—Drilling axle end. Fig. 7.—Assembling rear axle housing. Fig. 8.—Gun rifling machine.

operator revolves the casting until these graduations come in the center of the bosses when the holes will be drilled in the proper positions as the marks are opposite the bushings.

Ten 21/64 inch holes are then drilled in the housing, the drills being driven simultaneously as this machine is of the multiple spindle type.

Machining Rear Axle Housings

The next operation on the housing is performed with the jig shown in Fig. 5. The casting is located on the pin A and held with the nut as shown. In this tool the housing is revolved to the various positions where it is drilled, namely three, these in each case being determined by the man who machines the hole in the center of a boss as at B.

In this operation the following holes are machined, one hole for 1-1/2 inch 16 pipe tap, one hole for ¾ inch 16 pipe tap, one 1 inch drill this latter hole being also faced. For these operations the man revolves the casting and changes the guide bushing and drill for the proper size in question. Fig. 6 shows the next operation on the axle, namely, drilling at the axle end. The jig is placed onto the casting being again provided with a recess which fits into the turned register on the piece. The jig is then turned around on this register until the locating pin B will fit into the hole as shown, which was drilled in the previous operation; the jig is then in the correct relative position for the drilling.

Eight ⅜ inch holes are then drilled and as may be seen by referring to the illustration as the machine is of multiple head drilling type all holes are produced at once. Two of the elements that form a rear axle housing are then fastened together by means of a number of bolts and the assembled unit placed in the fixture shown in Fig. 7. The part is located with four dowels, two at each end, these locating mediums fitting holes drilled at the axle ends, this operation being illustrated in the previous half tone. Two large plugs are then tightened into the large holes at the axle ends and these plugs may be seen at A, the other at the opposite end of the housing. Screws at B, one on each side, are then tightened against the housing to assist in holding it securely against the machining stresses. With the piece located and held as described the upper face is machined with the tool C, the operation being performed in a boring machine as may be seen by referring to the illustration.

Boring the Axles

The half tone, Fig. 8, shows a gun rifling or boring machine which is used to bore out the axles. These forgings have been previously faced at each end and machined to the correct length.

At the same time in which the facing operation is performed each end is turned for a length of about three inches. The axles, the machine drilling two at once, are then placed in locating fixtures as at A being centered by the turned portions.

The axles are held and revolved by the machine in the usual manner by means of belts which may be seen at the rear end of the machine. The drills are fed into the axles and a 13/16 inch hole machined in each.

The drills are of the forced lubrication type which not only helps them to cut more freely but also tends to remove the chips from the hole. The length of hole is 36 inches, being through the entire length of the axle, lightening and strengthening the elements very considerably.

Construction Work of All Kinds On the Increase Throughout Canada

SINCE the beginning of the year, Canada has experienced a distinct revival in the building industry after a virtual stagnation which existed throughout the war years and into the post-war era. Prices of building materials as well as the high cost of labor seriously curtailed construction of all kinds, and confined it to such as was absolutely necessary. With the establishment of a new level in the price of material and the readjustment of the cost of labor a decided impetus was given to the building industry from the opening of the building season. There has been unsurpassed activity, and the figures for the first six months indicate the accomplishment of a volume of construction unequalled in any year since 1914.

For the first six months of the year 1922, says a recent C.P.R. report, building permits in Canada had an aggregate value of $132,452,000 as compared with $111,763,500 in the first half of 1921, $144,747,100 in 1920 and $78,118,300 in 1919. In 1922 the Province of Ontario accounted for $74,586,900 of the total permit value; Quebec $31,294,200; the Maritime Provinces $5,521,700; and the Western provinces $21,049,200. Of the total the sum of $53,435,300 is accounted for by residential building; $39,660,900 by business construction; $10,050,700 in industrial erections; and $29,305,100 in engineering construction.

Increase of Over Twenty Million

Compared with the year 1921, the total value of permits throughout Canada shows an increase of $20,688,500 over the value of the same period. In Ontario the value of construction undertaken has practically doubled, and Toronto has led all Canadian cities in the building undertaken so far this year. The even distribution of the kinds of building undertaken is clearly illustrated in the figures for June 1922, the value of permits, $35,620,400, being the second largest monthly figure since May, 1914. Of the total, residential building accounted for 36.4 per cent.; business, 29.1 per cent.; industrial, 13.8 per cent.; and public works and utilities, 20.7 per cent. The amount of contemplated new work throughout the Dominion at the end of June was $26,117,400.

The buildings undertaken during the first six months, from coast to coast, are summarized as follows:—69 apartments, 95 churches, 124 factories, 195 public garages, 23 hospitals, 54 hotels. 103 office buildings, 46 public buildings, 10,725 residences, 243 schools, 823 stores, 24 theatres, 88 warehouses, 79 bridges, 19 dams and wharves, 103 sewers and water mains, 161 roads and streets and 138 general engineering.

Activity in General

The resumption of building in Canada is not confined to certain sections but is general, and exceptional construction activity is evidenced in all cities from coast to coast. According to the reports received from 56 Canadian cities there is a building increase of over 30 per cent. in comparison with 1921. Quebec Province reports an increase of more than fifty per cent.; and Saskatchewan shows an increase of more than 300 per cent. Montreal and Toronto, particularly the latter, have exceeded by a wide margin the value of permits for the same time last year. In Winnipeg the permits for the first six months of 1922 shows an increase of practically $1,000,000 over the corresponding period in 1921. In Calgary, for the same space of time, the million dollar mark was passed. Improvements are noted in Regina, Moose Jaw, Brandon, Lethbridge, Edmonton and other western centres, as well as Halifax, Moncton, Sherbrooke, Westmount, Fort William, Kitchener, Oshawa, Peterborough, and other cities of the East. In construction already accomplished this year, the leading cities in order are Toronto, Montreal, Winnipeg, Hamilton, Windsor, Ottawa, Vancouver, Quebec, London, Saskatoon, Port Arthur and Calgary.

The resumption of building in Canada on a substantial scale, more so than perhaps any other factor, may be taken as an indication of the return of brighter and more settled times and a further emerging from post-war depression, for building in the Dominion is so indicative of progress and expansion that it has come to be a gauge which marks, in a fairly accurate manner, the trend of economic affairs; it estimates the status of business and reflects the prosperity of other industries. In a resumption of building is reflected the downward trend in the price of all materials used in building, and a decline in the cost of labor to a level closer approximating the pre-war level. More building is indicative of hope and faith in the immediate future. No other disturbance of the years following the war caused such inconvenience and upheaval as the cessation of building, and, in view of all it portends, nothing is so gratifying as the return to a normal amount of construction.

Rapid Production of Gears by Hobbing Process

Continuous Cutting Movement—Even Distribution of Generated Heat—One Passage of Hob Completes the Gear—Special Arbors for Different Types of Blanks—Automatic Indexing

PRODUCTION of gears by the hobbing process requires the employment of a hob cutter, which has the form of a worm. When the hob is set at the angle of its helix, the teeth on the front or cutting side are parallel with the axis of the gear being cut. When the machine is operating both the gear blank and the hob are rotated together at the ratio required by the number of teeth in the gear and the pitch of the threads on the hob. The cutter feeds through from side to side, the hob cutting its path through the blank, and generates the tooth form on the entire periphery. The work is completed at one passage of the hob. A hob of a given pitch can be used on any size gear where the teeth are of that pitch.

The continuous cutting action of the hobbing process has the advantage of an even distribution of the heat generated around the entire periphery of the blank. This condition permits of high production owing to the fact that greater operating speeds can be used. Where gears are made in large quantities, this method proves highly efficient. It is essential however, to provide the necessary facilities for producing accurate work. Rigidity of the blanks being cut is a very important factor, and due consideration must be given to the class of arbor on which the gears are held during cutting operations. In the construction of the work holder care should be taken to see that the gear blanks are supported just below the root of the tooth; this is necessary to reduce the possibility of chatter and provide adequate resistance to the thrust of the cutter.

Arbor for Thin Blanks

Fig. 2 is a line sketch of a built-up arbor for carrying a number of thin gear blanks. Those shown in the cut are 8.222 in. outside diameter, 9 pitch diameter, 72 teeth. Twelve gear blanks are mounted on the one arbor and large washers are provided, the outer edge of which comes just inside the bottom of the tooth space. These gears are for automobile cam shafts, on half inch face and made of machine steel. The diameter of the hob used was 3 in. and operated at a speed of 146 r. p. m. with a feed of .070 in. for every complete turn of the work. The time required to reload the arbor was 2 min. while the actual cutting time was 49 min., giving a production of 113 gears in a day of 8 hours.

Data and cuts through courtesy of the Cincinnati Gear Cutting Machine Co.

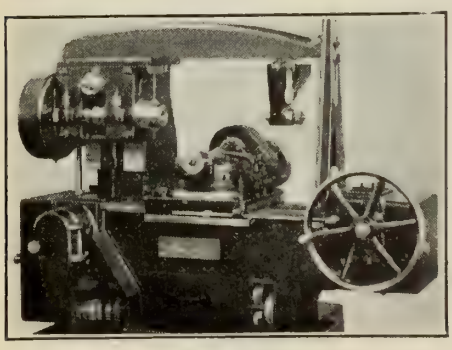

Fig. 1.—The hobbing machine.

Chain Sprockets

The sketch Fig. 3 shows the type of arbor used for the cutting of chain sprockets for 1¼ in. pitch, ⅝ in. dia. rollers, this chain being ⅝ in. wide. The outside diameter of the blanks is 4.671 in. and the number of teeth is 10, and 1¼ in. pitch. The sprockets were made of .20 carbon cast steel with a small percentage of nickel. Two blanks were mounted on the one arbor, which gave a length of cut of 2¾ in., with an over travel of .31 in. The over travel was small owing to the fact that the teeth were cast in, thus leaving about ⅛ in. metal to remove on each side. The hob used was 3½ in. dia. with an angle of 7 deg. 26 min., operating at a speed of 170 r. p. m., or 156 ft. per min. The feed per rev. of the work was .60 in. The time required for finishing two sprockets was approximately three minutes against four minutes for the former method. Hobs were ground every 8 hours. Note the intermediate washer used for supporting the tooth portion while being cut.

Cutting Ring Blanks

An interesting job for the gear hobber is shown in Fig. 4. This shows 12 ring blanks mounted on a special arbor, the outer portion being made of cast iron of the box pattern, giving maximum rigidity with minimum weight. The gear blanks are made of soft steel with a bore of 13.9485 in. dia., 11/16 in. face, 120 teeth of 8.10 pitch. These gears were cut with a 3 in. hob operating at a speed 170 r. p. m., or 134 ft. per min. The feed per rev. of work was .060 in. The time required for reloading was approximately 5 minutes per string, and 106 minutes required for the actual cutting of the 12 gears; this figured out at 9.25 minutes per gear. Thus, the production per day of 8 hours came to 52.

Production Record

Fig. 5 shows a group of gears, all of which have been produced on the hobbing machine. Fig. 6 is a tabulated record for each of the gears indicated by the respective numbers. For instance, No. 9 is a tough steel gear 10.-566 in. outside diameter, 1¾ in. face, 21 teeth. The hob has an angle of 45 deg. R. H. spiral and operates at a speed of 59 r. p. m. The feed per rev.

GEAR NO.	OUTSIDE DIAM	PITCH	NUM. OF TEETH	WIDTH OF FACE	SPUR OR SPIRAL	R.P.M. OF HOB	FEED PER REV. OF WORK	MATERIAL	TIME EACH GEAR

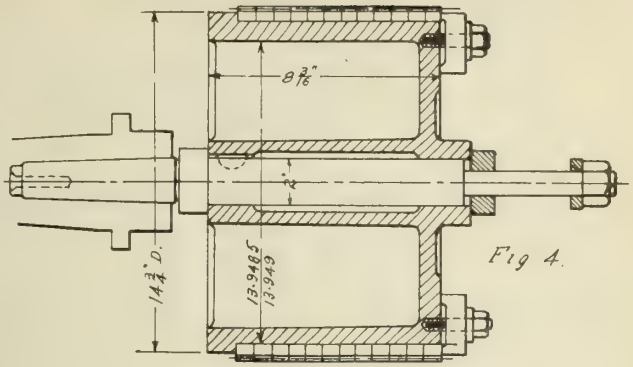

Fig. 4.—Special arbor for large ring gears.

of work is .03867 in. and the approximate time required for each gear is 48 min. While the time given is for individual it does not mean that these are cut singly; in the majority of cases they are cut in strings of from four to twelve.

The Hobbing Machine

The machine on which these gears were cut is shown in Fig. 1. This tool is readily adapted to all spur gears within its range. This hobber will take care of right and left hand spirals up to an angularity of 45 deg. The setting up for spiral cutting, however, is of such a character that rapid production is not attained when making single gears, but when large quantities of one style of gear are required the advantages are amply evident. The metal in the frame is so distributed as to provide the greatest stiffness possible, a factor that contributes to the accuracy of the machine, increasing the life both of the machine and the cutting hob, as vibration is one of the greatest destructive forces of metal-working tools and equipment.

The work spindle is made of hammer-forged steel, accurately ground, and supported in two long bearings in the work saddle. The work arbor is supported by a bracket that is carried by an overhanging arm, which in turn, is supported by a triangular brace extending up from the bed of the machine. An auxiliary bracket is suspended from the overhanging arm to assure alignment of the arbor support after reloading. The vertical movement of the work saddle is adjusted to height by means of a crank handle, the position being accurately determined by means of a graduated dial reading in thousandths.

The hob slide is supported on a wide base with a long narrow guide which reduces the tendency for the slide to build. The hob spindle may be swiveled in either direction from its normal position to an angularity of about 50 deg. for spiral cutting. The hob spindle is bronze bushed and adjustable for wear. Provision is made for lateral movement of the hob to use all cutting positions before regrinding. Automatic stops are provided by which the machine or the feed mechanism may be stopped at any point.

PROPERTIES OF MATERIALS

Under modern practice it is now possible to investigate materials by X-rays to a thickness of 4 or 5 mm. for lead; 12 mm. for tin; 7.5 cm. for carbon steel or iron; 12 to 15 cm. for aluminum and its alloys, and from 20 to 40 cm. for wood. Progress in this direction is rapid. Major G. W. E. Kaye, in his Cantor lecture at the Royal Society of Arts mentioned that it is now possible to get a photograph through an inch of steel in rather less than a minute using 130,000 volts with a few milliamperes through a Coolidge tube. Investigation by X-ray is of special value in electric and oxy-acetylene welding, of which it is a severe critic. Again, X-ray investigation promises to be exceedingly useful for the detection of hidden cracks; also for diagnosing defective soldering or brazing; the substitution of one metal for another, the hidden corrosion and defects in gas cylinders, ferro-concrete, the armouring of cables, and so on. The ideal aimed at to-day is to make X-ray photographs as easy and automatic as taking an ordinary photograph. But great improvements will have to be made before it can become a commercial process in heavy engineering. The great merit of the process is that it enables a much clearer idea of the properties of materials to be obtained without damaging the specimen in any way. Furthermore, it provides in some cases the only means of detecting concealed defects in the material without sacrificing any part of the structure, and also of ascertaining the accuracy of assembly of component parts of structures.

THE GOVERNMENT'S CONVERSION SCHEME

The attention of the holders of the five and a half per cent. war loan bonds maturing December 1, 1922, is directed to the offer of the Minister of Finance to renew the loan on favorable terms. The last Canadian loan was placed in New York at a satisfactory price. The Minister is making his present financial operation entirely a domestic one by offering to exchange the maturing bonds for new bonds bearing the same rate of interest, running for either five years or ten years as the bondholder may prefer. A further inducement to the investor is that he receives a bonus of one month's interest. The terms offered are decidedly favourable to the investor and it is probable that a large part of the maturing loan will be renewed. Arrangements for the exchange of the bonds can be made at any branch of the chartered banks. Holders who do not wish to reinvest will be paid in cash on the 1st December.

Improved Business Expected in Many Centres

Steady Improvement Reported From Different Boards of Trade —Industrial Commissioners Review the Situation—Unemployment Less Acute—Farms Absorb Labor—New Industries Locate

ENCOURAGING reports continue to come in from all parts of Canada, regarding the industrial improvement of the past few months and the prospects for steady betterment during the fall and winter season. The automotive industry apparently is the pivot around which general business is turning to-day, as there has been a more than normal activity in all motor lines. The coal and rail difficulties have caused a noticeable slowing up in different quarters, but the better tone of recent negotiations gives reason for a more optimistic feeling throughout trade circles. The following statement received from F. Maclure Sclanders, Commissioner of Industries for the Border Chamber of Commerce, is typical of others from different centres.

"It is questionable," states Mr. Sclanders, "if the industrial development of any other Canadian community has ever exceeded or even paralleled that of the Border Cities during the past five years. For instance, on 31st December, 1917, the total number of our industrial power consumers was merely ninety; whereas, on the thirty-first of last month this total had expanded to no fewer than three hundred and fifty. In other words, the number of power-using industries in the Border Cities has practically quadrupled well within five years.

"Many of our larger concerns commenced here on quite a humble and obscure scale. Apparently, however, their experience demonstrated the advantages of the Border Cities from a manufacturing standpoint, for the whole history of our industrial life has been one of expansion after expansion. The obscure industry of yesterday has become the great one of to-day.

Big Increase in Population

"Of course, you remember that the Dominion census of 1921 gave these Border Cities a population increase of over 138 per cent. for the decade. As a matter of fact, however, practically all of such increase occurred during merely half of that period. It is well within the mark to say that our population, which is now about sixty-two thousand, five hundred, has doubled within the lifetime of a child scarcely old enough for the kindergarten class. Correctly speaking, ours has not been development in the ordinary acceptance of the term: it has been transition swift, substantial and astonishing. This circumstance renders one just a little diffident in any attempt to indicate, even in the most conservative manner, the actual facts of our phenomenal unfolding. Why? Because the general public is inclined to look upon one in my position as a wildly optimistic booster whose utterances must be drastically discounted. In this regard, I can only say, on the threshold of my sixteenth year in the present line of work, that I have never yet made one statement that was not less and not more than the literal truth. Exaggeration is poor policy. It is wiser to understate so that when those who are interested visit your community and see everything for themselves they are agreeably surprised rather than disappointed, because in most cases, such people assume exaggeration.

"Our present activities compared with those of a year ago, show marked improvement — an improvement which steadily continues. Most of our factories are quite busy; some of them exceedingly so. Retail business is also brighter than for some considerable time, although it is not yet quite so active as we could wish. There is a great deal of building going on, just as has been the case for a number of years past. For instance, during the last three years, miles upon miles of entirely new paved streets, boulevarded and lined with nice houses, have come into existence; and the whole aspect of things here has changed in a sense that almost baffles.

Bustle and Life

"Further, and on every hand, there is an atmosphere of bustle and life and go —just such an atmosphere as one might have seen on the streets and within the stores of certain of the more progressive cities of our Northwest during the boom of 1910 to '12. The spirit of optimism prevails everywhere. It is an optimism not based upon real estate hysteria, but absolutely upon the sane, sound substantial foundation of industrial expansion—of actual weekly payrolls. Of course, our immediate propinquity to Detroit and many other neighboring United States industrial centres renders these border communities the logical Canadian location for United States plants, particularly such as have their headquarters in Michigan, Ohio, Wisconsin, Illinois and Indiana. As a matter of fact, almost all of our established industries are American. Consequently, it is United States capital and enterprise that is building here what will be, within a comparatively short time, one of Canada's few truly great metropolitan centres.

"Probably, it is because our development emanates from the United States that so many of our own people of the further east are still apparently blind to the wonderful things happening at this southern extremity of the Dominion. Only the other day, I encountered a rather emphatic example of such ignorance on the part of an ex-Dominion Minister—a gentleman popularly credited with a rather exhaustive fund of general information. He had visited the Border Cities some years ago, and it seemed the hardest thing in the world to convince him that, in the interval, everything had changed. As a matter of fact, the term 'changed' but inadequately indicates the situation. Complete metamorphosis is what really has happened. The things of yesterday and the long-familiar landmarks are now passed away, and have become little more than a memory and a dream. It is all wonderful.

Factories To Locate

"As to our industrial prospects—we always have probably eighty of these on hand upon which we are working thoughtfully and continuously. That a comfortable percentage of such will materialize sooner or later, we have every hope. It often takes a long time to bring in a new industry. Quite recently, we secured one upon which I had been working for five years. It is strange so many municipalities seem to think that all an industrial commissioner has to do is to throw his tooth brush and pyjamas into a handbag, rush down to the United States, and in forty-eight hours, return with several new industries duly signed up for his particular town. The industrial development of any community takes time. Such work is largely cumulative; not sensational. It is very thoughtful work.

"As to the outlook for the coming winter—we are in no sense discouraged. For the past five years, we have patiently and successfully developed an exceedingly nice export trade. Thus, our eggs are by no means restricted to one basket. In no sense, are we wholly dependent upon Canada's comparatively trifling domestic market of merely 8,788,483 prosperous people. We are feeling out into all the markets above which the British flag flutters and upon which the sun never sets—markets involving one-quarter of the inhabited globe and possessing a population which, according to the latest estimate, is placed at 445,388,500 souls.

"I contend that the solution of Canada's annual unemployment problem is the development of her export trade. Some day, this fact will be generally recognized. In this country, as in most other countries, domestic business is largely seasonal. Our factories are busy for certain portions of the year and quiet for the rest of the time. But, it is always summer somewhere. Our two coldest months are South Africa's two hottest and so forth.

"In conclusion, we have no apprehensions as to next winter. On the contrary, our whole outlook for many summers and winters to come—in fact, our entire

horizon—is far brighter than I have cared or, perhaps, dared to indicate."

Better Than a Year Ago

"While manufacturing and employment conditions are still below normal," states C. W. Kirkpatrick, Commissioner of Industries and Publicity, Hamilton, Ont., "they unquestionably show considerable improvement over the conditions of a year ago, with every prospect that, with the exception of some fluctuations during the winter months, the gradual improvement will continue and that by the spring of 1923, normal conditions will have been restored, to be followed by a period of prosperity.

"This appears to be the consensus of opinion of Hamilton's manufacturers, who are undoubtedly in a more optimistic frame of mind than they have been since the industrial depression began to set in about two years ago. This optimism is partly due to increasing orders, and largely due to the prospect of a bumper crop, not only in the western provinces, but throughout the whole country.

"Unemployment is not nearly so acute as it has been, but it is scarcely expected that there will be abundant work for all during the coming winter months. Since early spring the majority of industries have been slowly but steadily increasing their working forces, but they have not been able to absorb all of those who were idle during last winter. Many of the latter have found temporary employment on the farms and in the building trades, which have been unusually busy, but with the coming of winter these will again become shop workers, providing there is work for them to do.

Rapid Recovery in Textiles

"The textile industries have probably made the most rapid recovery, the majority of them having been quite busy for some considerable time, with no indications of an immediate falling off. On the other hand, the steel and iron industries have not yet shown any great activity, although even with them there are promising signs of improvement. Agricultural implement manufacturers are looking forward to the busiest winter they have had since 1918-1919. The majority of them have allowed their manufactured stocks to become almost depleted, and with the prospect of a rich harvest ahead they are beginning to give consideration to the restocking of their warehouses, in order that they may be in a position to reap the fruits of the harvest when the crop is marketed.

"An early settlement of the United States coal and railway strikes would unquestionably go a long way toward restoring confidence in Canada, they constituting the darkest cloud Canadian manufacturers see in the horizon at the present time.

"Like most other places, Hamilton has not enjoyed a particularly good year for industrial expansion. Fourteen new industries have been located since the beginning of 1922, but nearly all are operating, or getting ready to operate in a comparatively small way, and with but a few exceptions, they represent the investment of Canadian capital only. Few new industrial buildings have been erected, the manufacturer hesitating about making unnecessary capital expenditures until conditions become more settled. There have also been fewer inquiries from American manufacturers who are figuring on locating branches in Canada. So long as conditions are below normal at their parent plants, the American manufacturers are not likely to give much thought to expansion in the Canadian or other distant markets. Those American manufacturers who have investigated Canadian manufacturing conditions and the Canadian market this year, invariably make it clear that they were merely taking advantage of the dull times at home to gather information for their later guidance.

"One promising feature of the industrial situation is the increasing number of inquiries being received from British manufacturers and investors, there being many indications of an early influx of British capital to Canadian industrial centres. Taking all in all, industrial and employment conditions are much better and the future outlook much brighter than was the case at this time a year ago."

Better Trade in the East

In a statement received from R. E. Armstrong, secretary of the St. John, N. B., Board of Trade, the following extracts appeared:

"Industrial conditions in this locality are showing improvement in several lines. Lumber shipments throughout the province have been greater than for several years. It is expected that about all the surplus lumber that has been piled up everywhere awaiting shipment will be cleaned up. This means more activity in the saw mills and the promise of a fairly large lumber cut the coming winter. The pulp mills are beginning to function, but there is still a large surplus of pulpwood scattered throughout the province. Building conditions have considerably improved. Many summer dwellings have recently been built in the attractive suburban centres, and in the city itself there is an increase. Building permits for the first half of 1922 in the city proper reached a total of $308,000 as compared with $80,400 in 1921.

"Last month the Stephens Brick Co. reopened the old Lee Bros. brickyard on Little River road, East St. John. This plant, which years ago was recognized as one of the best in the province, has not been functioning for several years past, owing to the extreme age of the operators and the light demand for brick. The Stephens Co. purchased the whole outfit recently and have supplied it with modern and efficient equipment. The plant was formally re-opened July 28 by a banquet which was presided over by Lt. Governor Pugsley. Its prospects are good. The plant is capable of turning out 50,000 bricks per day.

"The sugar refining business of the Atlantic Sugar Refineries has greatly improved this year. About 600 hands are now employed. During the first six months of this year 34 steamers with raw sugar cargoes, amounting to 99,623 tons, have been discharged at the refinery pier. For the same period last year 9 ships, carrying 18,905 tons raw sugar reached the port. The quantity of refined product exported the first half of 1922 amounted to 48,904 tons, which required 49 steamers, while in the same period last year 5 ships carried out 16,128 tons. For the twelve months from June 1, 1921, to June 1, 1922, the total number of steamers that the Atlantic Refineries were responsible for at the port numbered 114, of which 47 landed 124,331 tons of raw sugar, 9 landed 38,622 tons coal, and 51 carried out 66,531 tons of refined sugar. This is a good showing and the refinery is still functioning actively.

"Development work is proceeding along active lines in Courtenay Bay, where the concreting of the new dry dock and the dredging of basin and channel are giving employment to about 350 hands. Crop conditions throughout the province are very favorable. On the whole, the industrial situation here is encouraging."

Sarnia Trade is Fair

Writing from Sarnia, Ont., Geo. P. France, manager of the Sarnia Chamber of Commerce, writes:

"Conditions for the past month in this district are fair, although there has been a reduction in the number of employees reported by two or three industries.This reduction was probably caused by the effect of the coal and rail strikes on the general marketing conditions. The industries working at normal capacity, compared with the same period last year, include petroleum products, structural steel, gray iron castings, threshing machinery, lumber and sawing, brass forgings.

"The labor turnover has been greater than last year for the month of July, and the turnover for the seven months of this year is greater than for the same time in 1921. There have been more men employed in the building trades and in the groups covered by shipping, but the manufacturing trades have been about the same, while the number of men registered as unplaced are not great as compared with the same period of 1921. The building permits for July are 38 with a valuation of $76,701, as compared with $85,000 for the same period in 1921. The building this year will show more small residences have been built and more local improvement to private homes than last year. Conditions in the building trades are quiet at present."

The Port of Oshawa on Lake Ontario may soon be a port of call for large vessels, as the Government has practically announced its willingness to vote the sum of $500,000 for the improvements to the harbor and docking facilities.

News From the Welding Field

Autogenous Welding Standards in Railway Practice

General Rules for Using Apparatus—Five Important Factors Are Condition of Surfaces, Bevel of Sheets, Position of Sheets, Expansion and Contraction, and Proper Filling Metal

By J. M. CALMBACH

IN order that greater uniformity and better results may be obtained in preparing work and making welds, the following methods and practices have been selected after considerable study, experiments and personal observation of the welding work in many shops throughout the country. They are considered the best and most practical methods in use to-day and are recommended as standard practices, to be followed as closely as local conditions will permit. Each foreman and welder who follows these instructions will find his work more reliable and satisfactory.

In welding cast iron, brass, cast steel and forgings, all such work should be fire heated whenever possible to insure a better weld, as well as to save gases. That is to say, all parts that take considerable time to heat with the torch sufficient to commence welding should be pre-heated so that when the welding flame is applied the part to be welded will respond almost immediately. As the oxy-acetylene torch cost per hour is extremely high it is easy to see that the heating of ordinary heavy parts with the oxy-acetylene flame is a very expensive operation and should be eliminated as far as practicable.

All foremen in charge of such work should use good judgment and take a personal interest in this matter and see that the proper provisions are made and work carried out accordingly. The preheating of cast iron, brass and other heavy castings is not only necessary for the saving of gases and time, but is also necessary in many cases to take proper care of expansion and contraction.

Five Essential Factors

In making a successful weld there are five very essential and important things to consider: (1) the condition of surfaces; (2) the bevel of sheets; (3) the position of sheets; (4) provision for expansion and contraction, and (5) proper filler metal.

The importance of these points cannot be overestimated and the failure to comply with the instructions covering any one of them will result in a questionable or bad weld. The success of a weld depends on the rigid observation of these items.

When sheets and patches are to be applied extreme care should be taken that all defective parts are cut out and also that they are cut so there will be a good foundation for the weld.

All sheets and patches should be cut on a straight or uniform line, avoiding staybolts wherever possible so that staybolt threads may be cut in unwelded plate.

Never cut out sheets or patches through the old weld where sheets have been welded previously. For side sheets or three-quarter door sheets, extend the new sheets at least one staybolt row higher; for crown sheet, one staybolt row lower; for patches, at least one row of staybolts larger; for the flue sheet, extend the weld to one row of staybolts lower.

Do not cut out sheets or patches and bevel sheets at the same time. If the sheets are to be beveled with the torch before chipping, this can be done after the parts are cut out; this is necessary to insure a uniform line, as well as a more perfect fit of the new parts.

Clean Surfaces Necessary

Clean surfaces are absolutely necessary for making good welds. If scale, rust, or grease is permitted to remain on the surface to be welded a slag is formed that will make a streaked and seamy weld. All surfaces must be kept free from foreign substances; all welding surfaces must be kept clean and bright.

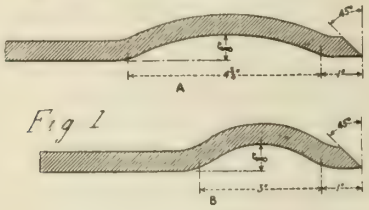
Experience has proven that the most satisfactory angle of the beveled faces preparatory to making the weld is an angle of 45 degrees with the surface of the sheets. The total angle between bevel faces must be 90 degrees in all cases, even if one sheet has to be beveled more than the other. Improperly beveled sheets prevent the welding flame from penetrating to the bottom of the weld and so prevent the weld from uniformly uniting with the edge of the sheet.

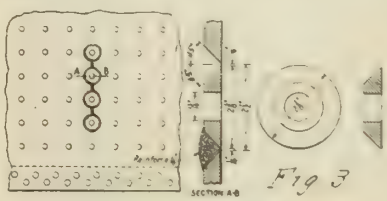
Where horizontal welds are to be made with the electric welder, it has been found good policy to bevel the bottom edge to about 60-degree angle and the top edge to about 30 degrees.

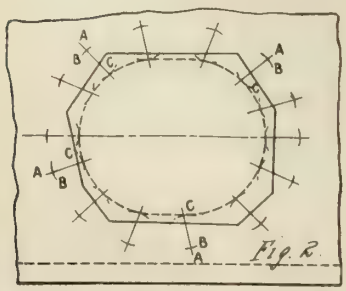
Fit Edges Carefully

All sheets and patches are to be fitted carefully with an opening of $\frac{1}{8}$ inch, no more and no less, between bevel edges. Less than $\frac{1}{8}$ inch opening between the sheets will not permit the welding flame to penetrate the weld properly and a greater opening requires too much filled metal to be used, not only increasing the cost of the weld, but making it impossible to keep the surface of the weld opposite the torch smooth. This rough surface permits lamination and seams on the water side of the sheet, weakening the weld and permitting early corrosion of the metal which tends to part the sheets.

Material prepared by the author and printed in Railway Mechanical Engineer.







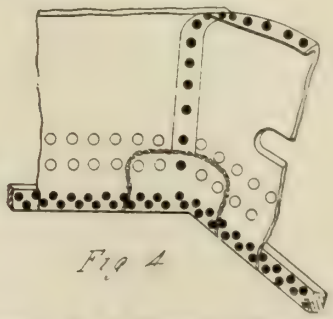


Fig. 1.—Standard corrugations for boiler sheets and patches. Fig. 2.—Method of laying out patches for welding. Fig. 3.—Method of welding cracks through staybolt rows; gas. Fig. 4.—Application of mud ring corner patch; gas or electric.

All other precautions may be carefully made and yet a faulty weld will be made if due care is not taken to allow for expansion and contraction of the sheets. Where it is not possible to obtain the necessary expansion and contraction through curves of the adjacent sheets, it is then necessary to provide some method to take care of expansion and contraction. In this case all sheets and patches will be corrugated, as shown in Fig. 1. A strain on a weld, especially where the new sheet is welded to an old sheet, which is generally the case, is particularly harmful as the old sheet will not stretch as much or as uniformly as the new one.

Bolting Patches In Place

When fitting corrugated sheets or patches, they should be bolted securely in place and when they extend to the mud ring good drift pins should be inserted in the mud ring holes so that the sheet cannot move upward due to the contraction as the contraction should be taken from the corrugation. Bolt the sheets at the welding end as usual. That is to say, insert a ⅝-inch bolt through every fifth staybolt hole and screw in a staybolt from the outside between each of the ⅝-inch bolts, thus holding the sheets in line. Then insert small wedges between the welding edge spaced about 14 inches apart to keep the sheets from pinching together during the welding.

Where side sheets are to be welded at the end it is necessary to remove the adjacent row of staybolts to the edge of the flange of the door of the flue sheet before welding is commenced. It is also advisable to remove all staybolts adjacent to welds after the welding is completed.

When welding corrugated sheets or patches with the oxy-acetylene method the following instructions are to be carried out: With every 12 inches of welding completed, the operator will stop and heat a line 1 inch through the center of the corrugation to a red heat and continue this until the weld is finished.

No firebox welds should be reinforced more than 1-16 inch as too great a re-inforcement is injurious to a weld due to overheating when in service.

Firedoor Patches

For firedoor patches when collars are to be welded they should be cut out at a point where at least one row of staybolts is in the patch and as nearly round as possible. When the patch is cut out at a point 6 inches or more from the firedoor edge it should be corrugated all around as shown in Fig. 5. It will not be necessary to corrugate if the patch is cut out less than 6 inches from the door hole. When firedoor patches are extended to the mud ring and 6 inches or more from the firedoor edge the patch will be corrugated all around. Where patches do not extend to 6 inches from the firedoor edge, it will only be necessary to corrugate both sides of the patch from a point about half way from the firedoor down to the mud ring.

The welding of cracks in side sheets, door sheets, firedoors, crown sheets, bottom and top of flue sheets should never be attempted as such attempts have been a source of much trouble and many engine failures. However, it may be considered necessary at times to weld certain cracks. This practice should be resorted to only in occasional emergency cases and then such work should be classed as strictly temporary and be corrected at the first opportunity. It is, of course, known that such work as welding cracks in the barrel of a boiler, welding over staybolts and welding staybolts is strictly against the law and will not be allowed at any time.

When it becomes necessary to weld seams that have given away, such as those between door or flue sheets and side sheets, the rivets should be removed and the outside of the fire side lap should be cut off through the center line of the rivet holes. Do not cut the side sheet and see that it is cleaned thoroughly before welding is commenced. Weld the holes solid and lap weld sheets.

Fitting, Preparing and Welding Fireboxes

For fitting, preparing and welding a firebox without removing the back end, the firebox should be set up on the floor with all staybolts and mud ring rivet holes drilled, except the mud ring corner holes, which would be drilled after the sheet is up and welded. The welding edge should be chipped to a 45-degree angle and chipped on a straight line so as to insure a uniform opening of ⅛ inch between the welding edges. The lower portion of the sheet from a point about 14 inches from the bottom of the flue and door sheets should not be chipped until the box is in place and the mud ring corners in place.

Bolt the sheet securely in place, being sure that there is a uniform opening of ⅛ inch all around the welding edge. Use a ½-inch drill and drill holes spaced about 14 inches apart, using ½-inch machine bolts with clamps made of boiler plate ½ inch by 2 inches by 4 inches. Use one of these pieces on each side of the sheet, being sure that all bolts are drawn tight. Rivet the top of the flue sheet to a point not less than 12 inches below the center of the crown; start welding at a point about 10 inches below the rivet and weld up to the rivets. Then drop down 10 inches and weld up to the end of the previous weld. Continue this operation until completed, removing clamps when necessary. Weld the entire door sheet.

Examples of Boiler Shop Weldings

The method of making corrugations for side and door sheets to allow for expansion is shown at A, Fig. 1. The corrugation for patches is more pronounced and is shown at B in the illustration. In laying out patches previous to welding it is sometimes difficult to cut them accurately unless some such method as the following is used: After the sheet has been cut out and beveled, the lines A, Fig. 2, are scribed as shown. With the dividers set at about 6 inches arcs B are scribed from the edge of the bevel. When the patch is ready to lay off for size, it is bolted firmly into place, as shown in Fig. 2. The lines A are then scribed back on the patch a short distance. With the dividers set at the same distance used before and with the intersections of lines A and B as centers, arcs C are scribed on the patch. Where these arcs intersect lines A, are points on the edge of the patch. A smooth curve is drawn through these points and the patch cut to the line. It can then be beveled and welded in place in accordance with the standard practice at local shops.

(To be continued.)

Practical Ideas From Practical Men

REPAIRING A CEMENT FLOOR

By D. A. Hampson

We have a cement floor in our shop —a first-class floor. It has been down nearly twenty years and about the only wear is that at the joints. The floor was laid the full width of each bay, in sections six feet in length. That brings the joints at right angles to the longitudinal aisles, which is naturally the direction of the most trucking.

Now whether the joints are laid with some elastic material between them or not, there always exists a joint and the sides are going to crumble if subjected to blows. Walking over the joints will not do this but trucking will and the joint that is cracked off one-quarter of an inch to-day will show a bell-mouthed top two inches wide in six months. All types of trucks—elevating, push, and hand—with metal wheels add to the ever increasing space at joints and there comes a time when the bump, bump, is more dangerous to the wheels than is the wear to the floor.

We had suffered a moderate amount of wear on our floors but it was not serious until we got in a class of work that was handled on trucks and that imposed wheel loads of from 250 to 500 lbs. each. As the gaps increased, we ran the risk of a serious accident in case a wheel broke. It was not feasible to use rubber-tired wheels on our work even if we were starting in with a brand new floor.

It was decided to make a general repair of worn joints in aisles and to that end a gang was put to work on them one Saturday morning. All the joints in the trucking lanes that showed more than a quarter inch of break were selected for repairs. Parallel lines were scratched on the surface spaced two inches apart, and cuts two inches deep or more were cut the full length of the breaks. The sides and bottom of these cuts were thoroughly dampened to make the new cement adhere better; then, a 3 to 1 mixture of sand and cement wa poured in and smoothed off level or a little above. (Strictly speaking, "cement" floors are "concrete" floors, though the language of the trade does not restrict as closely as in the machine business).

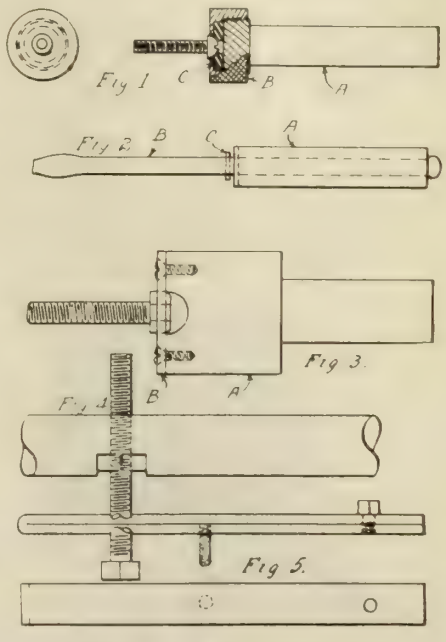
Wherever a joint was broken out more than two inches wide, the cut was swerved to include all of the bell mouth. On Monday morning, the joints were hard. What projected above the general floor level was worked down with emery bricks—it was considered better to do this than to finish off the fresh cement level with a trowel. The resulting job was extremely satisfactory and a year of service finds it, as good as on the first Monday morning. It is quite common to see floors repaired by pouring a little neat cement into the cracks as they are; this will not stay—it has not body enough and it tapers off to thin edges—in fact, the whole thing will be gone in a month's time. Make a good wide, deep cut, chiseling the sides down square from a sharp edge on top—then the job will last under severe daily trucking.

RAPIDLY DRIVING THREADED PARTS

By Harry Moore

If the jig and fixture principle is judiciously applied to the operation of driving nuts, screws, etc., many assembling jobs can be done at a speed proportionate to the rate at which the various parts are usually produced in the shops. Not infrequently, however, the operation of assembling consumes an amount of time out of proportion to the rate of production of the separate pieces and sometimes this is so merely because certain operations have always been performed in one set way and nobody cares to experiment on attempted improvements.

Take, for instance, the everyday job of driving button headscrews; it is rare indeed that anyone attempts to insert these other than by the well-tried screw driver route; yet, the shape of this particular screw head lends itself very nicely to the adoption of a very simple quick-driving fixture, and, where the parts are numerous enough, the one shown in Fig. 1 is well worth making. This is a drill press fixture, the body A being adapted to be gripped in the drill chuck. A knurled packing nut B tightens against a rubber or leather washer C, the hole in the washer being about ⅛ in. for screws over ¼ in. and the hole in the nut being large enough to admit the screw head. To drive a row of button head screws wth this device, the screws are first of all inserted by hand a thread or two, then with the drill press running at a fast speed each screw head is pressed up into the washer. The screws can be driven to seat in this way in a flash, the final tightening being made with a hand screw driver. It will be obvious of course that the screws must be an easy fit in the work to allow a device of this kind to be used and where this is not the case the machine screw driver shown at Fig. 2 is more applicable. In this instance also the body A is turned to fit the drill chuck of a press. Through the centre a hole is drilled to take the screw driver B, this being turned with a ball top and drilled for a pin C which engages in a slot in the bottom of A. In use B is held still while the machine is running and the blade inserted in the screw slot. A quick upward pressure engages C with the slot and drives the screw to the seat, final tightening being effected as before. Due to the fact that a positive drive is obtained in this case, provision is made to upset the driving action in the event of the operator failing to release the screw before it reaches the seat. This is effected by pin C being of light construction and the fact that the slot in which it engages is wide enough to allow it to clear if it bends; which it does if too much strain is put upon it.



Methods of driving threaded parts.

A very simple form of drill press tool is shown at Fig. 3, made for the purpose of driving long cap screws. The body A of this tool fits the drill chuck also, while near the bottom end a hole is drilled through at right angles of a diameter equal to the distance over the corners of screw heads. This piece is then chucked up and faced off until half this hole is left. Next a plate B is screwed to A, this plate having a hole in the centre equal to the distance over the corners of screw heads. This forms a guide for the screw head as it is pushed up, the drive taking place when the head strikes the half hole through the side. The screw is released immediately the upward pressure on the screw is stopped, final tightening being done with a wrench as usual.

Fig. 4 shows a simple tool made to run down a large number of lock nuts. This consists of a length of cold rolled about 12 in., drilled in the centre to clear the screw and slotted across the width of the flat on nuts. With the

screw head gripped in the vise a nut can be run down into a position near the head in a quick manner by merely giving the tool a spin. The weight of the bar will carry the nut over parts where it might have a tendency to stick. In the last example Fig. 5 a stud-driving tool is shown which spins the studs into place in the same manner as the bar shown at Fig. 4. Flat stock is bent double in this case, both ends being brought close together. One part is drilled and tapped for the stud and near the open ends a tightening screw is placed. In use the stud is inserted in the central tapped hole, spun into place and tightened. To release the wrench the screw A is loosened which allows the top leaf of the wrench to spring upward slightly and thus release the work. Screw A must be tightened each time a screw stud is inserted so that, when the latter is being tightened up it forces the head against the top leaf thereby creating a tension between the two leaves which forces them to spring slightly apart when screw A is released.

THE CHISEL AS A CUTTING TOOL

By G. Blake

In these days of machine tools covering every phase of engineering work, the chisel does not hold the position it did in the days of our fathers and grandfathers; yet, notwithstanding all the improvements and machines for dispensing with hand work of every description, there still exists a wide field for the scope of the chisel. But while the chisel is still an indispensable tool in the workshops, it would appear, however, that the workmen of to-day lack that skill (born of years of practice) in using it as did their fore-fathers. It is not the author's intention to descry the capabilities of the present-day mechanic, as he is not in any way responsible for the general conditions in our workshops affecting the adoption of labor-saving appliances; his lack of that adeptness with the chisel merely reflects the march of progress. As previously indicated, there still exists a wide field for the useful chisel, and with that object in view, the author desires to present in this article a few useful hints regarding the cutting angles for different materials. The cutting angle of the chisel is just as important as it is in the case of lathe, planer, and slotter tools, etc.

First let us take for example the chipping of a piece of mild steel or wrought iron. Fig. 1 shows a chisel correctly ground for cutting the above materials; the cutting angle it will be noted is between 30 deg. to 35 deg. included. Now, while this is approximately the best cutting angle for cast steel, mild steel, wrought iron and some kinds of non-ferrous metals, a chisel ground as in Fig. 1 is totally unsuitable for cutting cast iron. While the author was an apprentice in a small jobbing shop, he learnt the art of chipping, and bears on his hands to this day one or two reminders of his early attempts. One of the things he noted was that when chipping mild steel or wrought iron, the chip came away much easier when some form of lubricant was introduced; this lubricant was merely a drop of machine oil kept in a small cut made by the chisel on a block of lead. To apply it, the fitter merely dipped the extreme point of the chisel in the oil every few minutes. It is indeed surprising the difference a small drop of oil makes and how much less power it requires to perform the work. Of course we use lubricants on our cutting tools on the lathe, planer, shaper and drill, etc., for reasons that are too obvious to go into. The chisel is also a cutting tool and requires lubrication as do the others. To those who are familiar with these facts, it may seem rather elementary, yet, on the other hand, there are a great number of mechanics at the present time who are not conversant with these small but important matters.

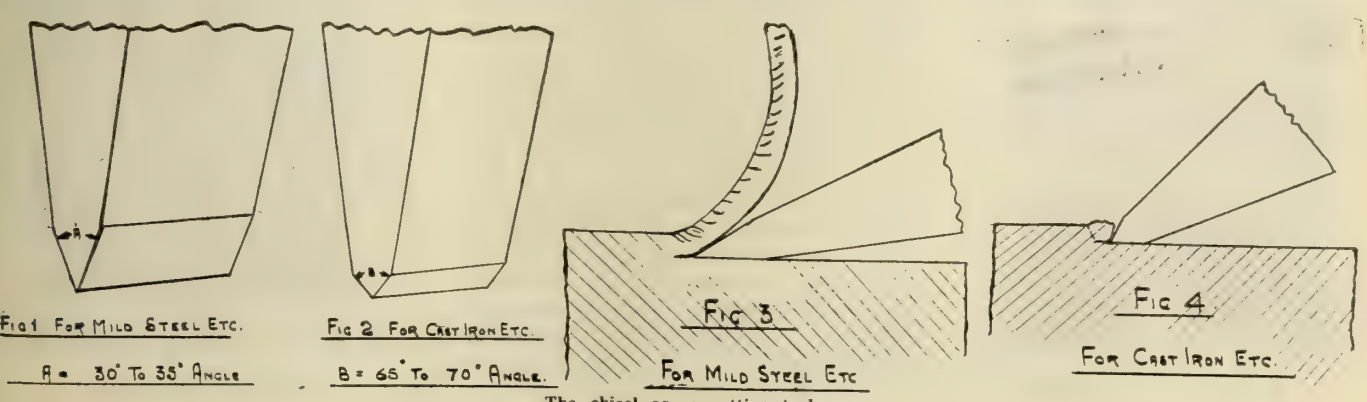
Fig. 2 illustrates the type of chisel suitable for cutting cast iron and some grades of non-ferrous metals such as phosphor bronze, etc. In this case, the best cutting is approximately 65 to 70 degs. included, and this angle, while eminently suitable for the above metals, would not give good results on cast steel or mild steel, etc. No cutting lubricant is required, as, in the case of all machine tools working on these metals; the best results are obtained without the addition of lubricants.

Figs. 3 and 4 diagrammatically show the action of the chisels for cutting mild steel and cast iron respectively. It will be noticed in Fig. 3 the cutting edge resembles a wedge; the angle is between 30 to 35 deg. included. If the angle is less, say 20 to 25 deg. the chisel would cut very much better, but on account of its long taper it would not stand up to the work for any length of time; either it would break or bend up at the cutting edge, so a compromise is effected by adopting the greater angle. The formation of the chip it will be noticed curls up as the work proceeds. Now, if a chisel with a cutting angle of 65 to 70 degs. is used on the same material, the chip would not have room to get away or curl up, it would come off in small lumps, forced off rather than cut off, making the work twice as hard to perform and giving a very poor finish.

Fig. 4 illustrates the chisel for cutting cast iron, etc., the included angle in this case being between 65 and 70 degs. This angle is best suited for the material mentioned, the grain of which, being altogether different, so that it is not possible to be cut off in long chips or shavings like mild steel. The action of the chisel in this instance is more one of forcing or dislodging small lumps from the surface, and the work is consequently harder and slower and requires more effort on the part of the workman. If we increase the angle to 90 deg. it becomes increasingly difficult to dislodge the metal, because it is necessary to have a slight undercutting, as in the case of Fig. 4, so that the metal will come away without as much effort as in the 90 deg. angle chisel point; therefore the most suitable angle is somewhere between 65 and 70 degs. If we come down to 45 deg. and 50 deg. and approach the angle of Fig. 3 we get too much undercutting; the chisel will be apt to rise at the point or to dig in deeper when the blow is applied.

A word now about the grade of steel suitable for chisels. Some people imagine that if the metal is cast steel it will make a chisel; this is not always the case, as one may select a piece of 1.5 per cent. carbon steel which is not at all suitable for making chisels. The best possible chisel steel for general purposes contains approximately .85 per cent. to .90 per cent. carbon; this steel will stand up where a higher carbon steel will fail. Thus it is extremely important to have the correct steel from which to make a chisel. Steel designed to withstand a succession of

(Continued on page 39)



The chisel as a cutting tool.

New Things in Shop Equipment

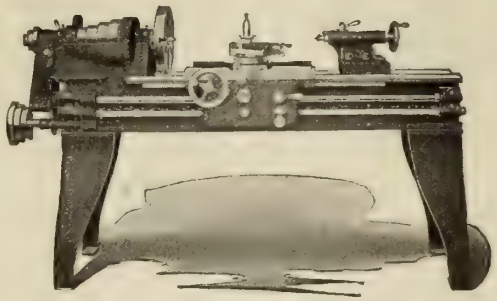
COUNTER WITH MEASURING ATTACHMENT

A counter that can be applied to any machine for recording consecutive moves of any part, or the number of pieces produced or passing a certain point, has been developed and placed on the market. The device can likewise be adapted to machines where it is desired to record the length of material produced, such as thread, twine, tape or wire. The material passes around an aluminum wheel which is secured to a shaft that, through a train of gears revolves a worm wheel secured to the spindle of the machine. A brass plate on the side of the worm wheel is graduated to read in feed—one full turn of wheel records 100 feet.

No lead gear, lock washers, ratchets nor springs are used in its construction. All gears are made of steel and parts subject to wear are hardened. The openings in the case are covered with a transparent fireproof material, which protects the mechanism from dust or dirt. The device can be operated electrically if desired. These small tools are made by the Precision Machine Co., Milwaukee, Wis.

STANDARD ENGINE LATHE

A new series of engine lathes, known as the "Standard," made in sizes from 14 to 20 in. swing, has recently been placed on the market. These tools are made both in plain and quick-change types, the beds being of the box-suction



14 to 20 in. "Standard" engine lathe.

style and recessed to permit tailstock to overhang at extreme end. Feed rods and lead screws are fitted to the lathe so that the lead screw is only in operation when threads are being cut. Accurate alignment of feed shaft and lead screw with the change gear box is assured by brackets being fitted in grooves on the frame. Racks are made in one continuous piece. Box type aprons provide double bearing for feed gear shafts. All apron gears are of steel integral with their shafts. The entire range of feeds and threads are obtained by means of two handles. The regular equipment of every lathe includes two faceplates, steady rest, follow rest, graduated compound rest, gear guards, and countershaft with two friction-clutch pulleys. Thread indicators, draw-in and taper attachments can be supplied when desired. These lathes are made by the John Steptoe Co., Cincinnati, Ohio.

SPECIAL GRINDING GAUGE

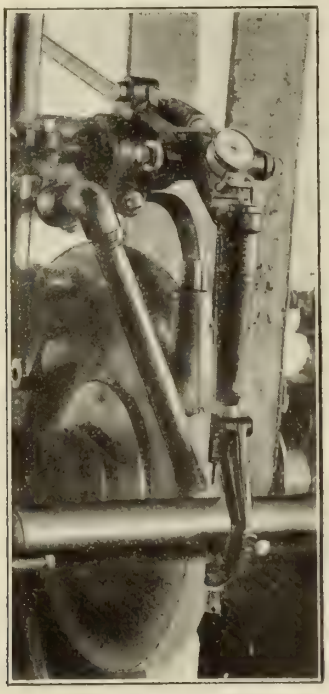
A gauge for determining the size of work being ground, without stopping it to use snap gauges or micrometers has recently been offered to the trade. The instrument consists of a cast iron body which contains a plunger and spring. An indicator is mounted at the upper end of the frame and interchangeable heads can be fitted to the lower end to gauge the different sizes of work. Each head has a sizing range of 1⅛ inches. There are three diamond contact points, two being fitted to the ends of adjustable screws and the third mounted in the end of the spring-actuated plunger. A very light spring pressure is required to keep the gauging points in contact with the work. The gauge is suspended between cone-pointed screws in a fork which is adjustable to any position. The bracket that supports the hanger mechanism is bolted to the grinding machine. The gauge can be used on all cylindrical work and the operation of sizing is quickly performed, because the gauge is always in a position for measuring. These gauges are made by Fred J. Pratt, Detroit, Mich.

EXPANSION HAND REAMER

A new form of expansion hand reamer, known as the "Parop" has recently been placed on the market. The adjustment is made by means of a taper plug regulated by a screw in the end. The end of the pilot is reset to a considerable depth for the protection of the head of the screw, and also to allow of placing the reamer offsetters for regrinding. Lubrication is provided for by an ample flow of oil through the squared end of the reamer through the slot to the cutting edges. The feature of the reamer is the shape of the flute, the alternate lands being parallel while the intermediate ones are set at an angle. It is claimed that this facilitates the honing of the cutting edges without the possibility of rounding over those on the adjoining edges. A short bevel on the end of the pilot is provided with a cutting edge to remove burrs from the holes when the reamer is entering. These reamers are made in standard sizes from one half inch to one and one half inches and are manufactured by the Gammons-Holman Co., Manchester, Conn.

STATIONARY DIE HEAD

There has recently been placed upon the market a stationary type die head with micrometer attachment. This head, with the micrometer attachment, is particularly valuable when cutting threads of special form which require one or more roughing cuts and a finishing cut.

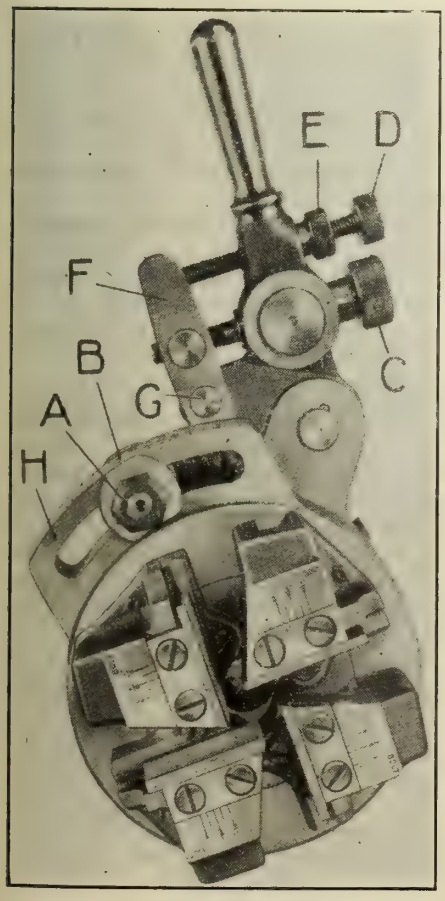


Grinding gauge in working position.

Gauge raised to clear work.

With this attachment it is possible to set the die head so that the same amount of metal is left for the finishing cut at all times. The head is graduated for both right and left hand for all sizes of bolts and pipe within its range. These graduations are stamped on the outer surface of the closing ring above the circular slot. To adjust the die head to size, loosen the clamping nut A, with the left hand and bring the index mark B, opposite the required graduation on the scale with the right hand. Further adjustment can be made, if desired, through the micrometer attachment. To adjust the micrometer attachment back off stop screw D, after first loosening the stop screw lock nut E, then the micrometer screw C can be adjusted for increasing or decreasing the diametrical adjustment. To increase the diametrical adjustment of the die head, turn the micrometer screw C, in a counter clockwise direction. This causes the upper part of the link F to swing to the left about the center G. The swing of the link F to the left pulls the closing ring H to the right and increases the diametrical adjustment. Turning the micrometer screw C in a clockwise direction causes a counter movement of the link F and decreases the diametrical adjustment.

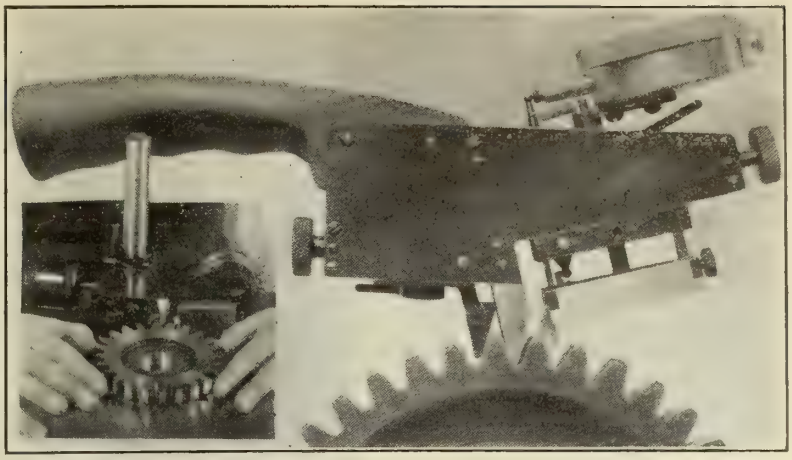
After the micrometer adjustment is made, the stop screw D should be set against the link F and locked in place with the stop screw lock nut E. To adjust the die head for the roughing cut, turn the micrometer screw C in a counterclockwise direction until the desired diametrical adjustment is obtained. The stop screw D should be left in the locked position. Two or more roughing cuts can be made by decreasing the diametrical adjustment of the die head in one or more increments through the micrometer screw C. After the roughing cut has been made, the micrometer screw C should be turned back in a clockwise direction until the link F comes against the stop screw D. The die head is now set to the final diameter and is ready for the finishing cut.



New stationary die head.

The die head with micrometer attachment can be applied to turret lathes, engine lathes, and hand operated screw machines. It may also be applied to all lathe types of threading machines where the work is revolved and the threading head remains stationary. To apply this head to a turret lathe, it is equipped with a shank to conform with the dimensions of the socket of the turret.

The application of this head to the cross slide of an engine lathe is effected by means of a special knee bracket. The front face of the knee bracket must be machined with a centering boss to fit the counterbore on the back of the head. The bore of the knee bracket should be concentric with the centre of rotation. This can best be accomplished by bolting the knee bracket to a cross slide and boring it out with a boring bar swung between centres. A special dead center will be required. The diameter of this special dead center must be such that it will have a neat fit in the bores of both the knee bracket and the die head. The length of the dead center should be sufficient to allow the front end to project through the bores of the knee brackets and the die head when the back end of the knee bracket is against the tail stock castings. This is necessary to enable the work to be swung between the centers in front of the die head. The work can be gripped in a chunk and threaded without the use of the centers, when the shape of the part makes this procedure necessary. These die heads are manufactured by the Landis Machine Co., Waynesboro, Pa.



Pratt and Whitney Odontometer.

ODONTOMETER

An instrument for testing the accuracy of gear teeth has recently been added to the line of precision tools. The Odontometer is a simple and self-contained instrument for testing the accuracy or uniformity of the gear tooth profiles and spacings of the teeth in production work. The instrument illustrated on the gear has a range of from 3 to 10 diametral pitch, may be used to check gears of any pressure angle, and can be applied to a gear while it is in place in the machine. In effect it is composed of a section of a straight-sided rack with two parallel effective faces. one fixed and the other movable. A third face, set at an angle to the two working faces, is used to hold the fixed working face in contact with the flank of the gear tooth. The fixed registering surface is at A, the movable indicating surface at B. The third surface C holds surface A in contact with the involute surface of the gear tooth. The surfaces B and C are adjustable so that gears of various pitches can be tested with the same instrument.

The indicating surface B is mounted on two thin flat springs D, which act as pivots free from backlash. The dial indicator E is actuated by the lever F, which has a ratio of 5 to 1, so that each division on the dial represents a movement of 0.0002 inch of the indicating surface B. In general the instrument is used as a comparator to test the uniformity of interchangeable and mating gears. If actual measurements are required, the distance between the two parallel working faces of the instrument can be measured. Stands are also made to hold the two smaller sizes of Odontometers when gears or pinion shaped cutters are being tested. In this case the gear is placed on the surface plate and rolled by the instrument. The actual cutting edge of cutters is tested, so that errors of whatever nature are detected. These gauges are made to check gears in the following range of sizes—¾ to 4 pitch, 3 to 10 pitch and 10 to 24 pitch. They are manufactured by the Pratt and Whitney Co., New York.

The Official Organ Mistake

WITH a lack of foresight which indicates an old-fashioned ignorance of the successful relations between a trade paper and the members of the trade it represents, the Timber Industries Council of British Columbia has decided to establish a journal of its own and arrangements have been completed under which the Pacific Coast Lumberman becomes the OFFICIAL ORGAN of the Council.

Apart altogether from the fact that the Pacific Coast Lumberman and the Western Lumberman have, in active competition, been giving the lumber trade of the Pacific a splendid service by maintaining healthy relations with the lumber consuming markets and that the manufacturers have now taken a questionable step in taking over one paper to be continued on competitive terms which can hardly be regarded as fair or equitable, is the conclusion born of experience that official organs defeat the very purposes for which they are conducted.

The well conducted trade paper represents various branches of the trade itself as well as the consuming public upon which that trade is dependent. Unless the relations between manufacturer, wholesaler, retailer and consumer are healthy business stagnates. To maintain such relations problems must be continually faced and solved. Many of them are unpleasant but their solution is the function of the trade paper which is properly serving its field.

The official organ must obviously serve selfishly the interests of the particular branch of the trade which controls it. If owned by manufacturers then wholesalers or retailers will not believe that it serves their interests; if owned by wholesalers or retailers, likewise it is regarded as their man Friday. In no case is the public interest likely to be properly respected. The result is that the official organ is conducted to please the people who are paying for its publication —and they usually pay heavily in the long run—and it is ignored by other sections of the trade with whom there should be co-operation and understanding in the interests of all concerned. Printers' Ink has effectively shown "Why Trade Associations Should Stay Out of the Publishing Business," and the following extracts are from articles which recently appeared in that publication:

When an association starts a periodical and goes out in the trade to solicit advertising, it is asking them to support a paper which is not founded on sound publishing principles.

A few associations decide that the independent papers do not "write them up" often enough and start their own publications so as to insure an unlimited flow of puffery.

The circulation is artificial; this circulation is generally mantained by virtue of the subscriber's membership in the association and is kept up regardless of the editorial merit of the paper.

Advertising in such publications is seldom sold on its merits. Seldom will the clever salesman remove the velvet glove from the mailed fist, but the hard iron of the implied threat is nearly always visible to the discerning buyer.

Such publications are of doubtful advertising value because of the difficulty inherent in the proposition of keeping the editorial contents on a par in reader interest with that maintained by a well-edited, independent paper.

When the lumber manufacturers of the Pacific Coast own their own paper they may expect to have their "fur rubbed the right way," but how can they expect this to improve those relations with the dealers which make for good business and mutual advantage? And when they advertise they should appreciate that they are paying to reach other manufacturers rather than the dealers who sell their goods and maintain the all-important connection with the consumer.

Stimulants For Better Business

IF ONE were to judge of general conditions from items appearing in the daily press and elsewhere, he must come to one conclusion and that is, business is improving. The fact forms a background of optimism which helps tone down the serious aspect of temporary labor problems. Here are a few selections from reports having reference to different phases of the industrial trend:—

"Factories get ready to meet big demands; busier day dawning."

"Labor outlook better. In some cases the demand for labor is greater than the supply."

"Western building record active for six months. Building boom reported on Vancouver Island."

"Furniture factories likely to have satisfactory business this Fall. Good demand for woodworking machinery."

"Large tonnages of structural steel moving. Active market for building material of all kinds."

"Boom expected in Canadian mining industry."

"Activity in Sydney mills. Billet and blooming mills now working double shift."

"Prairie crops promise well. One of the best we have ever had. Little else is lacking, but a good crop, to insure prosperity during the coming year."

Thus, it is seen, the general keynote is unmistakably that of prosperity. Slowly but steadily conditions are working back to a more satisfactory basis, and business seems to be doing well as the result of the stimulant. Orders are coming in from sources that have been inactive for months. The readjustments, losses and liquidations that have discouraged industrial effort for the past year or more will now, it is hoped, as the result of aggressive, well planned effort, give way to profit, and a more gratifying record on the other side of the ledger.

The amount paid out in accident claims in 1921 was $6,189,263. This is a large bill against the industrial pocket book and it will be gratifying to note that organization is gradually overcoming any tendency toward malingering or improper claims for compensation.

Premium Prices Indicated in Steel Market

Bars, Shapes and Plates Advance—Policy to Hold Prices Down to Encourage Buyers Has Disappeared—Canadian Furnaces Out of Pig Iron Market—Taking Care of Contract Business—Production Seriously Curtailed

PRICES ADVANCE IN RESTRICTED MARKET

PRODUCTION of pig iron and steel is declining as stocks of coal at steel mills and by-product coking plants play out. It would take weeks to restore the industry to a smooth running basis, no matter what the settlement of the present troubles might be. Shortage of coal naturally cuts down consumption of steel, and some consumers have curtailed their shipments, while others are urging heavier shipments as they see production falling off. When prompt lots are required, premiums of from $2 to $5 a ton are being paid, but the tonnages involved here are not large. This describes the condition in the basic American markets.

The Canadian situation is largely a reflection, or rather a result of the other. Canadian furnaces are practically out of the running so far as new business is concerned. Bookings, it is said, will run them into October, and they have suffiicent material on hand to take care of these. Meantime shortages are developing, not only in pig iron, but also in such urgent lines as steel and iron bars, and sheets of all kinds. Price trends are upward, but as yet the situation has not become so serious as to make advances a matter of unanimity. That is different houses, while apparently agreed that advances are opportune, are not agreed as to the time or extent of advances. It is a very firm market, with a growing demand for larger quantities.

From Pittsburg comes the report that the policy among steel mills to keep prices down, so that buyers would not be afraid to take hold freely after the coal strike, has disappeared. There is, of course, very little autumn business left to be done, and the average mill is pretty well sold up to the end of the year. Restriction of production means restriction of consumption and orders placed will therefore last longer.

It is considered doubtful if present prices of pig iron and steel products will hold for any length of time after industry again recovers its stride. Consumers tried to build up stocks at low prices, and it may develop that they have large tonnages of steel to liquidate. The minimum price on bars, shapes and plates, is now $1.80 or $2 a ton advance in a week, and $4 advance in 30 days. In sheets, some mills are practically out of the market, and the real trading market is confined to premium prices such as 2.60c for blue annealed; 3.40c for black; 4.40c for galvanized, and 4.85c for auto sheets. As to pig iron, there is reported to be scarcely any merchant production and consumption is restricted.

Machine tool business in Canada shows some evidence of improvement, and the demand is said to emanate not so much from large industries as from those whose plants are easily adaptable. This business calls for aggressive selling, but reports indicate a gratifying response. Machine shop supplies continue in good demand.

Toronto

August 16

THAT business is good and that there is a noticeable tendency on the part of buyers to consider larger quantities rather than the recent hand-to-mouth method of purchasing, is the statement of a prominent dealer in iron and steel on the Toronto market. He admitted that there were some inconsistencies in this tendency. It was difficult, for example, to reconcile the fact that prices are advancing, with the unmistakable evidence that bookings were heavier. The rail and coal strikes may, however, have caused an uneasiness as to the future and are naturally responsible for the determination to supply against future requirements. The trade is now confronting shortages, and the market is reaching that stage when anything but advance contract business must consider long prices.

Sheets and bars are in very strong demand, advances are the order of the day, and it is held by some that present prices on the Canadian market do not truly represent actual conditions. In some quarters they are held to be satisfactory while in others, more inclined to comparison with peak prices in American markets, it is the contention that prices must go quite a notch higher. It certainly appears that there is little if any concerted effort to maintain a dead price in certain departments of this market.

Pig iron markets reflect the difficulties of the present situation. So far as new business is concerned, Canadian furnaces, such as Steel Co. of Canada, and Algoma Steel Corporation, are out of the market. Their resources are said to be barely sufficient to cover contract requirements. The Port Colborne furnaces are also out of commission for the time being. The price quoted, $35.65, is said to be slightly better than the Buffalo figure, but as one buyer pointed out, this doesn't mean anything if the market is short, unless the quotation represents a premium on emergency business.

Scrap metal market: It would naturally be supposed that, with the shortage in the pig iron market, some improvement in the demand for scrap metals would be noticed. Reports indicate a decided flatness here, however. "We are governed by the American markets," declared a dealer, "but I will say that we are in a little better condition. There is, on the whole, very little to report. The market is weaker, for manufacturers who cannot get coal are not in the market for other materials. Given coal, the situation would soon right itself." Among purchases within the past few days were 500 tons of No. 1 machine cast iron at $21 for a Montreal account. Current prices are:

Copper, light ... ... per 100 lbs.	8 50
Copper, crucible	11 00
Copper, heavy	11 00
Copper Wire	11 00
No. 1 composition	9 00
New brass cuttings	6 00
Red brass turnings	6 50

Rails (scrap)	11 00
Malleable	11 00
No. 1 machine cast iron ...	21 00
Pipe, wrought ...	6 00
Car wheel	16 00
Steel axles	15 00

Iron and steel bars and sheets form a department in which activity may be said to have centred most decidedly. The demand continues to develop strength and prices are upward. Although the market does not appear to be unanimous, some houses give iron and steel bars a range from $3.25 to $3.40; small shops an advance from $3.25 to $3.40 and fine steel $3.15 to $3.40. Premier sheets are now quoted at $6.75, while zinc sheets, small lots, are quoted at $11. Latest quotations from Chicago show an advance of 10 cents on bars, shapes, plates, and small shapes, and it is predicted that there will be further advances. Current quotations are:

Iron bars	3 25	3 40
Steel bars	3 25	3 40
Reinforcing bars	3 25	3 40
Steel hoops		4 25
Tire Steel		3 40
Spring steel		7 00
Band steel, No. 10 gauge and 3-16 in base	3 65 to	3 75
Small shapes		3 40
Sheets, black, No. 28 ...		5 25
Sheets, blue ann., No. 10 ...		4 25
Canada plates, dull, 52 sheets ...		5 25
Canada plates, all bright		6 00
Galvanized Sheets, No. 28...		6 35

Non-ferrous metals, so far as the Canadian markets are concerned, are reported as somewhat inactive, and that the strike situation is making for more difficult conditions. Nevertheless, New

York reports strong consumption of all non-ferrous metals, with lead and zinc leading. France and Germany are reported to have bought large tonnages of copper recently. The zinc market has also been quite strong, with producers unable to extend owing to strike conditions. There have been slight advances in the American markets, where activity has been most pronounced. Tin has fluctuated considerably, but on the whole, there has been a recovery from recent reaction. The Toronto quotation is $36.50, indicating a slight advance. Aluminum is also showing strength with quotations around $22. Current quotations are:

Lake copper	17 25
Electrolytic copper	17 25
Castings, copper	17 00
Tin	36 50
Spelter	7 50
Lead	7 00
Antimony	7 40
Aluminum	22 00

Turpentine again figures in a slight advance from $1.75 to $1.85, while linseed oil, raw, scored a jump from $1.10 to $1.14. Gasoline is reduced to 34 cents.

An order for two hundred and fifty steel refrigerator cars for the C. P. R. is being executed by the National Steel Car Co., Hamilton. This will call for considerable tonnage in material. There has been a recent advance, about $3 a ton, on steel for this class of work.

Some business is being done in machine tools, and there is a feeling that the situation is gradually improving. It is not the kind of business that goes begging, however, but represents keen, aggressive salesmanship. Nor it it coming from the very large industries, but from those who are in a position to easily adapt their plant to opportunities as they occur. The demand for machine shop supplies continues on an encouraging basis.

Pittsburg

August 16

THE monthly report of the American Iron and Steel Institute, giving the steel ingot production of 30 steel companies in July, indicates that the steel industry, as a whole, produced steel ingots in July at a rate of about 36,000,000 gross tons a year, this comparing with rates of 36,600,000 tons in June and 36,400,000 tons in May.

The average rate in July quite misrepresents the rate of production, however. Production increased in the latter part of June, while about the middle of July there began a sharp decline in production, this decline continuing to date and promising to go considerably farther in the next two or three weeks if not for a longer time.

Considering the circumstances, it may be taken that the rate of production to July 1, was about 37,000,000 tons, the rate dropping to say, 34,000,000 tons by the end of July, and to somewhere in the neighborhood of 30,000,000 tons at the present time.

The influence of the combination of the coal strike and the railroad strike has become very serious. The steel industry got along very well during the first three months of the coal strike, which began April 1, increasing its rate of production by fully 5 per cent. Large stocks of coal had been accumulated, and there were heavy drafts upon non-union coal fields, particularly in West Virginia and Kentucky. The unusually heavy movement of coal from those districts began to congest the railroads involved by the middle of June, and when the railroad shopmen's strike began July 1, the condition was greatly accentuated. According to railroad officials the strike has been waning, but the receipts of coal are light as the congestion is not cleared. With these light receipts, and with stocks of coal at steel mills and by-product coking plants playing out at one point after another, production of pig iron and steel goes down. No conceivable settlement of the coal strike would restore the coal movement to the iron and steel industry except after the lapse of several weeks as it takes time to get shipments moving smoothly, and for a time precedence must be given to various consumers. and, in particular, the movement up the lakes to the northwest must be taken care of.

Consumption Restricted

Appearances are that steel has grown scarcer, but appearances are sometimes deceptive, particularly when one is dealing with the human element. The shortage of coal cuts down consumption of steel, but by how much no one is in position to estimate. Some steel consumers have notified mills to curtail or discontinue shipments of steel, on account of impaired consuming ability, but there may be many who wish to pile up steel so as to be safe in case they get supplies of coal sooner than the steel mills can increase production. Steel buyers are very human, and as a rule when they think steel is scarce they are anxious to get more.

Many customers of mills are urging heavier shipments, as they see production falling off. Some consumers are in the market to buy prompt lots, at the delivery premiums that generally have to be paid, say $2 to $5 a ton as a general statement. The tonnage involved in this prompt demand is not large, relatively. The premiums are insignificant compared with those paid in 1920 on large tonnages.

Two months ago the policy was largely in vogue among steel mills, although there were some exceptions, of holding steel prices down, the idea being that a safe market level should be preserved so that buyers would not be afraid to take hold freely after the coal strike. With a high market buyers would be likely to adopt a drastic policy of liquidating stocks, as they did in 1921.

This policy appears to have disappeared, if the present price advances are a criterion. One reason for abandoning the policy would be that there is scarcely any autumn business left to be done, for the simple reason that with production restricted the sales and purchases already made will last longer. The average mill is pretty well sold up to the end of the year, on the basis of its prospective production. If ability of buyers to consume steel is correspondingly restricted by coal and transportation conditions, the buyers in turn are covered for longer periods than they supposed a couple of months ago.

Will Prices Hold?

It is possible that when industry gets in smooth running order again, present prices of pig iron and steel products will hold, but that is extremely doubtful. The issue may not arise before the beginning of the new year and it is quite improbable that it will unless consumers have a considerable tonnage of steel now in stock to liquidate. They do not appear to have, from the way they act, but it is to be noted that for four months, April 1, to August 1, production of steel was at rate of over 36,000,000 tons of ingots a year, or 35 per cent. above the average rate in the first three months of the year and 85 per cent. above the average rate in 1921. Steel consumers were more or less fearful that the coal strike would cut down their supplies of steel, and presumably they tried to build up stocks, particularly as prices early in the year were low. The question is not so much as to their desire as it is as to their success.

The minimum on bars, shapes and plates is now 1.80c, this being $2 a ton advance in the week and $4 advance within 30 days. Prompt lots have gone at prices up to 2.00c and perhaps even higher. In sheets the old prices, based on 3.15c for common black, are still nominally in force by some mills, but these mills are sold up as far as they care to go and are practically out of the market, so that the real trading market is confined to the premium prices, say 2.50c to 2.60c for blue annealed, 3.30c to 3.40c for black. 4.30c to 4.40c for galvanized and 4.75c to 4.85c for automobile sheets. Hoops remain at 2.50c as a general base, but hoops under one-inch width are held at 2.75c, or $5 a ton premium.

Unfilled Tonnages

The Steel Corporation's unfilled tonnage statement shows that the corporation booked more business in July than was commonly estimated, and probably much more, proportionately, than did the independents. The unfilled obligations of the corporation at the end of July amounted to 5,776,161 tons, equivalent to 5½ months' production at 75 per cent. of capacity, the rate the corporation maintained during May, June and July. The increase during July was 140,630 tons, or 11 per cent. of the month's capacity, and estimating shipments at 75 per cent. the total bookings in the month appear to have been about 86 per cent. of capacity, against 103 p. c. in June 86 per cent. in May, 115 per cent. in

April, 90 per cent. in March, and less than 50 per cent. in each of the 17 months preceding, since September, 1920.

The whole pig iron market has dropped out, except for there being a market in small spot and prompt lots, prices for which are higher. Last sales were at $27 for Bessemer, $25.50 for basic, $28 for foundry and $29 for malleable, f. o. b. valley furnaces, freight to Pittsburg being $1.77. There is scarcely any merchant production of pig iron, while consumption is restricted. Neither producers nor consumers are in mood to consider transactions for forward delivery.

PRESENT DAY PROBLEM

(Continued from page 23)

necessity of reconciling annually the figures shown by the books with those shown by the tax returns. On the other hand established bookkeeping procedure, adopted for valid business reasons, would thereby be upset and valuable comparisons rendered impossible.

One client who adopted the "cost or market" basis for his inventory decided to abandon the "cost" basis for bookkeeping, although that basis had been followed for years. He soon found, however, that to operate his cost system using cost or market was a complicated matter. The solution seems to me to be to keep the accounts on a cost basis and to make annual adjustments in the aggregate if it is desired to bring the accounts finally to a basis of "cost or market."

THE CHISEL AS A CUTTING TOOL

(Continued from page 33)

blows or impacts, does not contain more than .90 per cent. carbon at the most; this percentage of carbon just gives the steel that toughness which is essential in a good chisel. Many chisels are made from a higher carbon steel than suggested by the author; this, of course, leads to more frequent grindings, breakages and hardening than would be the case if the steel contained the correct amount of carbon. Chisels are very often overheated in the forging and hardening causing breakages and loss of time and money. With an .85 per cent. to .90 per cent. carbon steel it can be heated to a higher temperature, without affecting the metal, than a 1.25 per cent to 1.5 per steel, as carbon has the effect of making the steel brittle when found in the higher percentages. When hardening a chisel a good method of ascertaining the correct quenching temperature is to use a magnet on the part to be hardened. Carbon steel when heated to a certain temperature loses its affinity for the magnet, and this stage, it has been found, is the correct temperature for quenching. It will surprise one who has previously worked by the color of the steel when withdrawn from the fire, to see the low temperature at which steel will harden. Another method and an old one for hardening a chisel is to get it a dull red, and whilst in that state to drive it (quickly) point downwards into a block of lead; this gives the correct hardness without tempering. In connection with tempering a chisel, if the steel is of the correct carbon content and if heated to its proper temperature, it should be tempered to a deep purple color; this will make the chisel tough and yet hard enough for most kinds of work, but on very hard cast iron it may not stand up so well as on mild steel; in that case a purple with a golden tint will be found more satisfactory.

To sum up. The chief points to be observed in making and using chisels are: 1st. Get the right steel. 2nd. Correct heat treatment. 3rd. Correct cutting angles. A little perseverance and practice on the lines suggested will go a long way towards a better and more intimate knowledge of the "art of chipping."

ELECTRIC CONTROL OF PLANER

(Continued from page 21)

shunt field sufficient to reduce the current to half its maximum value. This prevents the field from over-heating when the motor is not in use. The extra start and stop station makes it possible to control the equipment from either side of the planer.

The general purpose of this, and similar controllers, is to eliminate the difficulty experienced when using the old line shaft method of drive, also to place in the operator's hands a complete and individual control of each piece of machinery by electrical means. This controller is designed to take care of and handle all conditions which may come up in the operation of a large planer, to provide safety for the operator, for the planer itself and the work upon which the planer is engaged. Conditions such as overhead, low-voltage or complete loss of power are automatically taken care of, and resumption of operating is easily and safely made in the simplest possible manner. The speed of the planer and the length of cut may be changed at will by the man in charge of the planer.

BRITAIN TAKES LEAD

In a recent report of trade conditions it was shown that the United States, which in the fiscal year ended June 30, 1921, was Canada's best customer by a wide margin, has been displaced by Great Britain. This was disclosed on June 30 of this year. During the first period Canada's exports to the United States totaled $502,000,000 and those to the United Kingdom $307,000,000. In the year covered by the latest report, Great Britain, with purchases amounting to $301,838,000, won first place from the United States, which shipped only $295,398,000.

MAKING A SCARF WELD

To make a scarf weld, the metal should be reinforced or upset, as far back as it is exposed to the intense heat. This upset allows for wasting away. In case of failure to make a perfect weld at the first heat, then a second heat should be taken. No sign of the scarf should be seen on a perfect weld. For ordinary lap weld the length of the scarf may be made one and one-half times the thickness of the bar. If the scarfs are long, the laps must be long. In welding a round bar, the scarf is made the same as the lap weld except that the scarf should be drawn to a sharp point instead of to a chisel edge. This is done in order that the corners may not project beyond the edge of the bar when welding, thus causing considerable trouble. Place the pieces in the fire with the scarf down, as the under side of the iron is always the hottest. Do not heat the iron too quickly as it will come to a welding heat on the outside and yet not be thoroughly heated, so that when exposed to the air, it will cool too rapidly. When each piece has attained a clean, white heat, remove them, giving each a jar upon the anvil while the scarf is down thus dislodging any dirt which may have adhered. Turn the one in the right hand over and place the other on top of it, bringing them together as quickly as possible. In putting the two pieces together, the point of one scarf should just meet the heel of the other. Hammer rapidly, in order that they may become united before the heat gets below the welding point. The cold anvil very quickly reduces the heat.

BENCH FILING MACHINE

A small motor-driven filing machine, manufactured by the Robinson Tool Works, Waterbury, Conn. has recently been improved in design. The top plate is supported in such a way as to permit of tilting to an angle of 10 deg. in any direction. An improved dust guard has also been added.

NEW STARRETT MICROMETER

The L. S. Starrett Company has out a new micrometer at a low price. This one inch micrometer caliper, No. 435, has a black enameled, drop-forged, rigid construction frame. Decimal equivalents are marked on the thimble. As the screw is .312″ in diameter and the contact points .270″, there is an unusually large wearing surface which insures long life. It is sold with or without ratchet stop.

In the operation of machinery it is very important to keep the slides well lubricated; not with excessive application but light and frequent. The dirt and dust that is generated by the cutting of cast iron soon absorbs the oil on the ways and they do not move freely. Before oiling the slides should be wiped clean.

News From the Industrial Field

Rienforced steel contract for the new car barns for Toronto Transportation Commission has been awarded to the Burlington Steel Co., Toronto.

The Dominion Bridge Co., Toronto, have secured the structural steel contract for the new addition to car barns for the Toronto Transportation Commission.

The National Steel Car Co., of Hamilton, recently secured a contract from the C. P. R. for 250 refrigerator cars and a number of large baggage cars.

The steel contract for the repairing of the Scholastical at Outremont, Que. goes to the Walsh Plate and Structural Works, Montreal.

The promising outlook in the glass business is the reason for a recent report that the Libby-Owens Sheet Glass Co., of Hamilton, would enlarge their plant to provide for double the present production. This concern produces for a widening export demand as well as a large domestic business.

The steel contract for the new $150,000 hotel to be erected at Campbellton, N. B., has been awarded to the Eastern Canada Steel and Iron Works, of Quebec.

The Joliette Steel Products, Ltd., of Joliette, Que., have acquired the plant and equipment of the Joliette Steel Co. The new organization will continue manufacturing the lines of the old concern in addition to their other products.

The Montreal Architectural Iron Works, 145 Prince St., Montreal, have obtained the contract for ornamental iron for the Presbytery and Sacristy on Visitation St. The value of the building is approximately $125,000.

Contracts will soon be awarded for the several new buildings to be erected for the Western University at London, Ont. These structures include a natural science building to cost $250,000. The arts building will require an outlay of $200,000, while the new central heating plant will cost about $25,000.

The Hayes Wheel Co. of Chatham, have recently acquired the plant and equipment of the Dominion Forgings and Stampings of Merritton, Ont.

The Trussed Concrete Steel Co. of Canada, have secured the steel contract for the $700,000 hospital to be erected for the Grey Nuns at St. Hyacinthe, Que.

One result of labor unrest in the States was shown last yeek when a train of fifty crippled locomotives from the Wabash system across the line were sent through to Montreal to be repaired. It is the first shipment of the kind since the U. S. strike commenced.

Jno. Watson and Son, 167 Wellington St., Montreal, have obtained contracts for the ornamental iron work on the new $141,500 school at Bordeaux, Que., to be constructed for the Catholic School Commission; also for a school to be built by the same commission in the vicinity of Montreal.

The coal strike in the States has resulted in greater production in other localities. Ninety-eight thousand tons of coal were shipped from Sydney piers last week, a new record, surpassing the boom days of the war. In addition, considerable bunker coal was loaded at Louisburg piers. It is expected that these figures will be surpassed by the present week.

CANADIAN BRANCH OF AMERICAN CONCERN TO BUILD AT BELLEVILLE

BY THE decision of the Bassick Manufacturing Company, of Bridgeport, Conn., Chicago, Ill., to establish their Canadian branch at Belleville, the latter city has secured its tenth new industrial location within the last fifteen months. Mr. E. W. Bassick, president of the company, and Mr. Fesler, general manager, were in Belleville last week and carried to successful conclusion negotiations for the purchase of the H. A. Wood factory and plant on Pinnacle St. Here they will introduce forthwith the manufacture of the well-known "Alemite" products now used as part of the standard equipment for motor cars and generally adopted by manufacturers throughout Canada and the United States. The company will also carry on in its new premises the manufacture of all the lines now controlled by the Bassick interests in the United States.

The principal lines produced by the Bassick Company are casters and furniture hardware. In these they are said to be the largest manufacturers, not only in the United States, but in the entire world. They have already established five important plants in the United States, the parent plant being at Bridgeport, Conn., the most important subsidiary at Chicago, Ill., and others at Meriden, Conn., Newark, N. J., and Cleveland, Ohio. The company also manufactures a considerable line of automobile parts and accessories, such as the Dole valves, locks, hood latches, and in particular vacuum tanks. They are also introducing a promising novelty in the form of a flexible metal shield for automobile springs. The necessary mechanical equipment for the new plant will be forwarded to Belleville at once and installed as soon as possible. It is the intention, not only to manufacture at Belleville all the Bassick lines, but to manufacture all the parts so that the Belleville factory will be far more than an assembling centre. It is expected that when fully established the company will employ several hundred hands and will probably carry on from this city its important European and Colonial export business, as the American Optical Co., which established at Belleville a few months ago, also intends to do. The Bassick Company will have an independent Canadian Corporation and the new company will be known as the Bassick Alemite Company of Canada.

BIG TWINE SHIPMENTS

Fort William.—To date, 1922 shipments of binder twine received at the local warehouses of the International Harvester Company and the Plymouth Cordage Company, exceed any other year's business in the history of the plants. Six steamship cargoes have been unloaded at the former house and five at the latter. The Plymouth people estimate the increase over last year as fifty per cent. The twine is being shipped to the Canadian West where it is being used upon the harvest fields of the prairies to garner the 1922 grain crop, as fast as it is received here.

The total shipments of twine here since the opening of navigation reach 44,000,000 pounds. At 550 feet to the pound, the twine if made into a single strand would measure 4,583,333 miles; long enough to circle the earth one hundred and eighty-three and a third times, or form twenty strands reaching from the earth to the moon.

F. C. Perry, for the past twenty-two years collector of customs at Fort William, has been superannuated. His successor has not yet been appointed but it is probable that a returned soldier will get the post.

Due to the consumption of coal stocks at Sault Ste. Marie, several cargoes of coal have been shipped there during the past week. The coal will be used for the purpose of coaling ships.

Fire which started from an undetermined cause, caused damage estimated at $20,000 last week to the Sellers and Jones garage here, not including the destruction of eight automobiles.

Arrangements are being completed for the establishment in Fort William of a bottling factory by the Orange Crush Company of Winnipeg. The proposed plant will have a capacity of 96,000 bottles a day.

Eighty-five acres of land in Neebing township several miles from the city, have been acquired from the Vickers estate by the Canadian National Railways. The price paid was $25,000. Fifty years ago the land was purchased by the late J. J. Vickers for $1 per acre.

Building permits issued here during the month of July totalled well over half a million dollars, the figures being $557,985. The permits include those issued for the new Paterson grain elevator, the paper mill now under construction for the Fort William Paper Company, and sixteen residences.

On Saturday, August 12, the new steel bulk freighter, Matthewson, built at the plant of the Port Arthur Shipbuilding Company, for the Matthews Steamship Company, Toronto, was launched. Mr. Matthews, president of the transportation company, his wife, and a party of Toronto citizens, attended the ceremony, arriving in a private car Saturday morning.

TO MAKE STEEL CASTINGS

Montreal.—Joliette Steel Products Limited, 211 McGill Street, Montreal, have taken over the property and plant formerly operated by Joliette Casting and Forgings Limited, plant of which is in Joliette, Quebec. The company will specialize in steel castings and alloy steel castings. W. A. McCallum will be in active charge of the company as vice-president and managing director and it is reported that he has large steel interests in Montreal behind him.

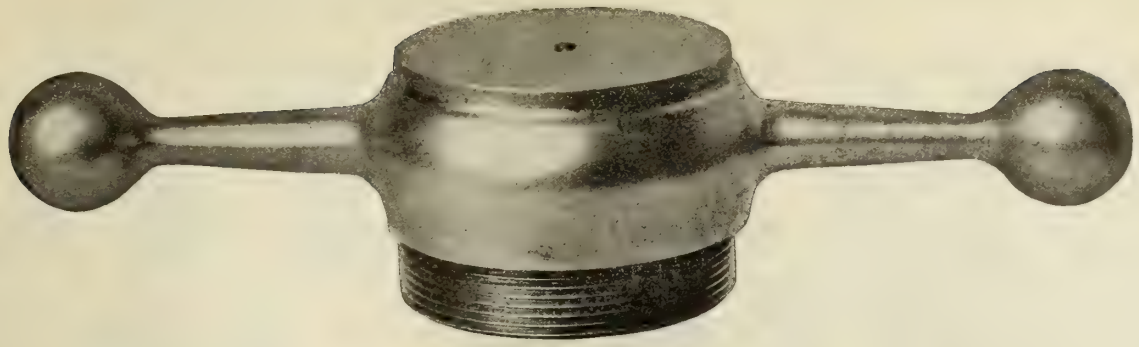
Mr. McCallum was born in Montreal, Que., April 21, 1891, and educated in public school and commercial technical school. His business career follows: Began as clerk, Consumers Cordage Co., Ltd., Montreal, 1906 to 1913; assistant to secretary, Geo. W. Reed & Co., Montreal, 1913 to 1916; assistant to vice-president, Canadian Tube and Iron Co., Ltd., Montreal, assistant to president, Canadian Rolling Mills Co., Ltd., and assistant to president, Colonial Wire Mfg. Co., Ltd., 1916 to 1919; (these three companies now constitute the Canadian Tube and Iron Co, Ltd.); appointed vice-president F. E. Smith Ltd., Montreal, Oct 1, 1919; appointed vice-president of the Independent Steel Specialties Corporation 1920; appointed vice-president Joliette Castings and Forgings, Ltd., July 2, 1920.

"BROOKLYN BRIDGE IS FALLING DOWN"

At last we learn that this historic structure may soon be definitely closed to traffic owing to the excessive stretching of the suspension cables, a condition that may cause the gradual disintegration of the entire bridge. No announcement has been made as to what action will be taken as a thorough study will be made before a decision is made. It is more than likely that immediate steps will be taken to construct a new modern bridge, even though temporary repairs are made to the present one to carry the light traffic, to which it is now restricted.

LARGE CHAIN CONTRACT GOES TO HANS RENOLD COMPANY

In connection with the handling and storing of the large grain crops in South Africa it is interesting to note that the contract for the chain drives for a large number of elevators has been awarded to the Hans Renold Co. of Manchester. This order, which includes 38 Renold silent chain drives for the Capetown terminal elevator, 50 similar drives for the Durban terminal elevator, and 184 extended pitch bush roller chain drives for the 24 country station elevators, is probably the largest single order for power transmission chain drives in grain elevators that has ever been placed.



15,000 THREADS

Cut with One Set of Geometric Thread Chasers on These Radiator Caps—a German Silver Casting—Not a Very Clean Casting, Either

Geometric Adjustable Thread Chasers are a small part of the Opening Die Heads and Collapsing Taps in which they are used, but they are an important part.

They stand up to the work—doing even more than is claimed for them, when rightly used.

"No sign of wear on the cutting face of a set of Geometric Chasers after cutting threads on fifty pieces of work, and from all appearances good for many hundred pieces without regrinding."

Such factory reports make Geometrics the Standard wherever they go.

New Case-Hardening Process

A NEW steel and iron hardening process has been developed, based on research covering a period of several years. The results obtained through this process are interesting. The hardening agent used is a nitrogeneous powder, marketed under the trade name of "Nitrol." The use of this material results in a nitrogen hardening, of which the advantages are obvious, but which thus far had remained undiscovered, other substances having invariably induced oxidation.

The Government Testing Laboratory at Berlin-Lichterfelde, in its annual report for 1916, while characterizing the hardening substances generally employed as practically worthless, expresses the opinion that this powder induces a very marked surface hardening, at the same time leaving the inner body unaffected. The report further states that various degrees of hardening can be obtained through the use of the material, and that it is possible to intensify the hardening process to such a degree that the surface must be ground off to permit file or saw to grip. In spite of this intensified surface hardening, however, the inner structure of the material remains in its original state.

The hardening result is not affected by the state of the surface; thus, even rusty objects can be surface hardened equally as well as polished ones. The carrying through of the hardening process is very simple, and can be handled even by unskilled labor. Another remarkable effect is that the surface after hardening is practically rust-proof. Nitrol is furnished in two grades, namely: "A"—being used for surface hardening, and "E"—for case hardening down to a depth of 4 mm. (about 3/16 in.

Sprinkling Powder "A"

This powder turns into a liquid state at the usual hardening temperature. When sprinkled on the heated object to be hardened, it liquefies and forms a thin uniform coating over the surface. A perfectly even and flawless hardened surface is the result, no insoluble particles remaining to mar the coating. The object having gone through the hardening process, and after being quenched, presents an absolutely flawless exterior of glittering brightness, the core, however, remaining absolutely unaffected. Such is not the case with the hardening substances heretofore in general use, as there are always present in them certain insoluble elements which, by adhering to the surface of the object, prevent an even distribution of the hardening material. A non-uniform degree of hardness, and a spotty appearance, is the result.

Powder "E" For Case Hardening

Through careful and prolonged experiments, it has been established that the best results in case hardening by this process are obtained with the hardening agent in a gaseous state. An extraordinary degree of uniformity and depth of hardening is thus attained without any smudging, forming of deposits or lack of uniformity. The hardened object, when removed from the case, will be found to have no particles adhering to it. After quenching, the penetration of the hardening will be found to be absolutely uniform. Here also, the core or inner structure of the object remains in its original state.

Through properly adjusting time and temperature, the depth and degree of hardness can be regulated. In most cases, a few hours of hardening will be found to serve the purpose, but the proper time and temperature required in each case depends on the quality of the materials to be hardened and the purpose to which it will be put.

Directions For Use

For shallow surface hardening the object should be brought to light red heat in an open or closed fire, then sprinkled with the powder or dipped in the material, at the same time turning the object around so that the entire surface will be covered. When the object has cooled down to the proper temperature, it should be quenched in water or in a saline solution in the usual way and dried off. Should the object have cooled prematurely while being treated, it should be held over the fire once more and then quenched. The surface will be found to be bright and hard as glass.

For case hardening the objects should be placed in cases packed with powder "E," and then heated in the usual manner up to 88 deg. C. for about two to four hours, depending on the depth of hardening required. The heated objects are then removed and quenched in the usual manner. The hardening powder can be re-used with addition of some fresh powder. The powder should be protected from any access of outside air while still hot, and it is advisable to pack it in air-tight boxes immediately after removing the objects to be hardened. Through the re-use of the material, a considerable economy is effected.

BRITISH FIRMS GETTING BUSY

Many British firms are now putting their men on full time, and it is stated that a very good spirit prevails amongst the men, who are working steadily and well under the conditions of settlement. The result has put new heart into the engineering industries, and considerably more optimism prevails than has existed for some time. The general depression shows signs of passing slowly away, but all estimates agree that it is bound to take a considerable time before trade can be regarded as normal. The brighter outlook is however welcomed by all persons engaged in trading in engineering products and it only needs a constantly increasing stream of orders especially from overseas to make it possible to reduce prices by manufacturing on a larger scale than is at present the case.

120 Dalhousie St., MONTREAL.
Grey Iron, Semi-Steel Castings up to 10 tons.

Can. Mead-Morrison Co., Ltd.,
MONTREAL, P.Q. WELLAND, ONT.
Grey Iron Machinery Castings.

Hugh Park Foundry Co., Ltd.,
OSHAWA, ONT.
Grey Iron, Patterns, Etc.

Hull Iron & Steel Foundries Ltd.
HULL, CANADA.
Steel, Manganese, Chrome.

Aurora Foundries, Limited,
AURORA, ONT.
Grey Iron.

Aluminum Last & Metal Co.,
KITCHENER, ONT.
Aluminum, Brass, Bronze and Special Alloys.

Can. Hanson & VanWinkle Co.
LIMITED
TORONTO, ONT.
Monel, Aluminum, Brass, Bronze, Grey Iron.

Tallman Brass & Metal, Ltd.
HAMILTON, CANADA
Brass, Bronze, Manganese Bronze, Aluminum.

Dom. Foundries & Steel, Ltd.
HAMILTON, CANADA.
Steel Castings all sizes.

Manitoba Steel Foundries, Ltd.
Office Winnipeg. Works Selkirk, Man.
Steel Castings up to 5,000 lbs.

Brantford Brass Foundry Co.
BRANTFORD, ONT.
Aluminum, Brass, Bronze, Specialty.

The Katie Foundry
GALT, ONT.
Grey Iron, Semi-Steel, Brass, Aluminum.

William Kennedy & Sons, Ltd.
OWEN SOUND, ONT.
Steel, Malleable and Heavy Grey Iron.
See Advertisement Page 8

Machinery & Foundries, Ltd.
BROCKVILLE, ONT.
Light and Medium Grey Iron.

A. F. McCulloch
OSHAWA, ONT.
Brass, Alum. Castings—Wood, Metal Patterns.

Corbet Foundry & Machine Co. Ltd.
OWEN SOUND, ONT.
Grey Iron, Brass.

Fittings Limited,
OSHAWA, ONT.
Malleable, Grey Iron, Brass, Aluminum.

John T. Hepburn, Limited
TORONTO, ONT.
Grey Iron.

W. W. Wells
370 Victoria Street, TORONTO, ONT.
Nickel and Monel Metal.

The Robert Mitchell Co., Ltd.
64 Belair Ave., MONTREAL.
Light Grey Iron.

Canadian Steel Foundries, Ltd.
MONTREAL, QUE.
Steel and Ferro-Alloy.

Langley & Austin,
GALT, ONT.
Copper, Bronze, Brass and Aluminum.

Maxwells, Limited
ST. MARYS, ONT.
Light Grey Iron, Tinning same a specialty.

The Eureka Planter Co., Ltd.,
WOODSTOCK, ONT.
Specialty Light Grey Iron.

Lindsay Foundry and Pattern Works, Limited
Victoria Avenue, LINDSAY, ONT.
Grey Iron.

Dominion Engineering Works, Limited
MONTREAL, QUE.
Grey Iron.

Smith's Falls Malleable Castings, Limited
SMITH'S FALLS, ONT.
Malleable.

Joliette Steel Co.
JOLIETTE, QUE.
Electric Steel and Ferro-Alloy.

International Malleable Iron Company, Limited
GUELPH, ONT.
Malleable.

BRANTFORD BRASS FOUNDRY COMPANY
BRANTFORD, ONTARIO
FOUNDRY AND OFFICE 22 LEONARD ST

June 27th., 1922

The MacLean Publishing Co., Limited.
Toronto, Ont.

Gentlemen;-

We wish to inform you that we have had quite satisfactory results from our advertisement in Canadian Machinery and Manufacturing News, which runs under the classified heading " Where to Buy your Castings ".

Yours Truly,
Brantford Brass Foundry Company.
per David McIntosh

Canadian Machinery BUYERS DIRECTORY

If what you want is not here, write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index— last page of book, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names undr proper headings is gladly undertaken, but does not become part of an advertising contract.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

Pay Us a Visit During the Exhibition

TORONTO
Aug. 26-Sept. 9

Here's a real chance to examine that new tool

While you're in Toronto for the Canadian National Exhibition you are cordially invited to visit us, not only at our booth in the Machinery Hall, but at our Headquarters.

You'll be welcome to wander at your pleasure around the 130,000 feet of floor space devoted entirely to machinery and supplies of all kinds. You are sure to see many machines that will be of special interest to you—it's an exhibition in itself.

Our headquarters and one warehouse is right next door to Union Station. Our other warehouse is at 27 Bathurst Street; cars for the eastern Exhibition entrance pass the doors.

Here Are A Few Facts

of interest to every buyer of machinery and supplies in Canada. The 130,000 feet of floor space in our Toronto warehouse is filled to capacity with machine tools and supplies of every description required in machine shops. Our lines include the best makes on the market. From our immense stock we are always able to meet requirements and our splendid shipping facilities enable us to fill all orders promptly.

Our experience extends over half a century. You can always depend upon securing satisfaction when you order from us. Get the habit of ordering from PETRIE—it pays.

Canada's Dependable Machinery and Supply House

H.W. PETRIE LIMITED

Toronto Hamilton

To Holders of Five Year 5½ per cent Canada's Victory Bonds

Issued in 1917 and Maturing 1st December, 1922.

CONVERSION PROPOSALS

THE MINISTER OF FINANCE offers to holders of these bonds who desire to continue their investment in Dominion of Canada securities the privilege of exchanging the maturing bonds for new bonds bearing 5½ per cent interest, payable half yearly, of either of the following classes:—

(a) Five year bonds, dated 1st November, 1922, to mature 1st November, 1927.

(b) Ten year bonds, dated 1st November, 1922, to mature 1st November, 1932.

While the maturing bonds will carry interest to 1st December, 1922, the new bonds will commence to earn interest from 1st November, 1922, GIVING A BONUS OF A FULL MONTH'S INTEREST TO THOSE AVAILING THEMSELVES OF THE CONVERSION PRIVILEGE.

This offer is made to holders of the maturing bonds and is not open to other investors. The bonds to be issued under this proposal will be substantially of the same character as those which are maturing, except that the exemption from taxation does not apply to the new issue.

Holders of the maturing bonds who wish to avail themselves of this conversion privilege should take their bonds AS EARLY AS POSSIBLE, BUT NOT LATER THAN SEPTEMBER 30th, to a Branch of any Chartered Bank in Canada and receive in exchange an official receipt for the bonds surrendered, containing an undertaking to deliver the corresponding bonds of the new issue.

Holders of maturing fully registered bonds, interest payable by cheque from Ottawa, will receive their December 1 interest cheque as usual. Holders of coupon bonds will detach and retain the last unmatured coupon before surrendering the bond itself for conversion purposes.

The surrendered bonds will be forwarded by banks to the Minister of Finance at Ottawa, where they will be exchanged for bonds of the new issue, in fully registered, or coupon registered or coupon bearer form carrying interest payable 1st May and 1st November of each year of the duration of the loan, the first interest payment accruing and payable 1st May, 1923. Bonds of the new issue will be sent to the banks for delivery immediately after the receipt of the surrendered bonds.

The bonds of the maturing issue which are not converted under this proposal will be paid off in cash on the 1st December, 1922.

W. S. FIELDING,
Minister of Finance.

Dated at Ottawa, 8th August, 1922.

The Business of

ALFRED HERBERT LTD

consists of two main divisions; viz., the "Manufacturing" and the "Factored." The first consists of two well-equipped, self-contained shops comprising Laboratories, Foundries, Machine and Erecting Shops, employing upward of 3,000 men in the production of Automatic and Turret Lathes, Milling and Drilling Machines. The second or "Factored" Division acts as sole selling agents in various countries for leading British and American makers of machine tools.

The combined result is an organization able to quote on the most suitable machines for any given work and to deliver them tooled up with all the necessary tools and fixtures. Complete Plants can also be quoted on for the production of complete units when desired.

SOMETHING NEW

IN

WELDING

You are cordially invited to visit our booth at the forthcoming Canadian National Exhibition, Toronto, (commencing August 26, 1922) which is situated in Machinery Hall opposite the main entrance.

In addition to our display of Oxy-Acetylene Welding Apparatus and Supplies we are showing Electric Welding Rods, both flux coated and plain, suitable for all classes of Electric Welding.

Features of special interest will be the welding of steel by Alternating Current using Special flux coated rods. Also welding Cast Iron Electrically with a patented flux Coated Cast Iron Rod giving a weld equal to that obtainable by Oxy-Acetylene Welding. Demonstrations of the use of these rods will be given continuously during the exhibition. We shall also demonstrate the use of all kinds of welding rods for general purposes, both Electric and Oxy-Acetylene, special equipment being installed for these purposes so as to make the exhibit as interesting to you as possible.

It will be our pleasure to give you all information possible on any point relating to autogenous welding, both Electric and Oxy-Acetylene. Expert operators will be in constant attendance and you can rely upon receiving a hearty welcome and courteous attention which will make your visit, we sincerely trust, both pleasant and profitable.

LONGEST SERVICE

We make these three right.

1. Exacting analysis of the physical and chemical properties of our steel insures a uniform product.
2. Intelligent workmanship constantly striving to produce the better tool yields the Pratt & Whitney quality.
3. Rigid inspection of the work in process and of the finished product guarantees tools for longest service.

The finished product must be right.

IDEAL FACTORY SITES

A RARE OPPORTUNITY—Seldom have we been able to offer manufacturers a location equal to the two factory sites shown in diagram. Both sites are very central, low in price and possess splendid transportation facilities.

No. 1—303 ft. 10 in. frontage; total area 31,500 sq. ft. The railroads have promised us that immediately land is purchased they will place a siding to suit purchaser's requirements. It will also be noted from sketch that this siding may be brought from the east on to the south side of this land, thus holding control over land fronting on Queen Street, and making the property we offer more valuable and profitable.

No. 2—A splendid location for small factory. Total area, 15,800 sq ft. Provided with rear entrance on which is a railroad siding that may be extended to suit purchaser. Both sites are steadily increasing in value. Purchase now. Reasonable offers given due consideration.

On your way to Toronto Exhibition stop off at corner of Dufferin and Queen Streets and view both sites—they are in close proximity. In the meantime write for particulars and prices.

How DIAMOND FIBRE and Condensite Celoron

CAN and is being applied to MECHANICAL-ELECTRIC and TRANSPORTATION FIELDS

"How can we apply Diamond Fibre and Condensite Celoron to our business?"

"Will the use of Diamond Fibre and Condensite Celoron reduce our cost?"

These two important questions are often put before us by manufacturers who frankly admit they do not fully understand the wide scope and uses of Diamond Fibre and Condensite Celoron. They are anxious to improve their product if either of our materials are suitable, and naturally they are desirous of reducing costs if at all possible.

In practically every case we are able to prove that Diamond Fibre or Condensite Celoron **WILL** suit their purpose and **WILL** reduce costs. If we do not think our product is suitable we SAY SO FRANKLY. We give only EXPERT ADVICE for we are SPECIALISTS in the business and our reputation has long since been established.

The uses of Diamond Fibre and Condensite Celoron are so varied that it is impossible to mention them all in this space, so we will, for the benefit of manufacturers, present a different use in every advertisement of this series telling of its successful application to the industry or plant as the case may be. We know you will be interested in this series for they will be Educative. Interesting, and be the means of showing the way to Greater Production. The first will appear in the October 5th issue.

Be sure and visit our exhibit at the Toronto Exhibition, August 26th to September 9th. We will show you the various uses of our products and courteous attendants will answer all questions.

For prices and full data on both these products, write to the

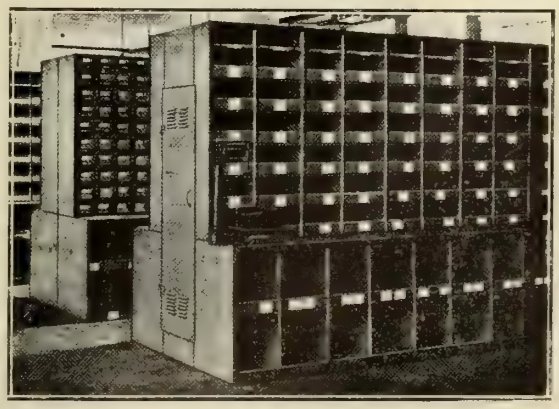
Diamond State Fibre Company

of Canada, Limited, Toronto, Ont.

If It's Made of Wire, We Make It!

WHEN in need of high-grade wire rope of any kind for any purpose, get in touch with us because we have facilities for making wire rope that are second to none. We combine the highest quality of material with the greatest degree of skill in manufacture. Good wire rope, such as we make, is far superior to hemp rope because it gives you greater strength under all weather conditions and is lower in cost in the long run. We make all kinds for all purposes.

In addition to our wire rope and wire cloth, we manufacture a complete line of clothes lockers, tool room enclosures, storage bins, etc., and one type, known as design "C," is shown in the illustration. Note the compact and rugged design, also the protection against fire.



This is only one style and we have many others to meet all shop and storage room conditions. The best thing to do is write for our catalogue and bulletins which give full particulars about our many lines.

When at Toronto Exhibition, come to our Hamilton plant and we will make you welcome and show you why we are proud of the goods we manufacture. We solicit your enquiries.

Efficiency

BLISS

To BE PROFITABLE the manufacture of small stampings made in large quantities must be extremely rapid with practically no loss due to rejections.

In the picture we show a BLISS No. 19½ Inclinable Power Press the production of which is 45,000 blanks a day. The operator and the character of the work are each factors in the production rate as well as the efficiency of the press. With BLISS Presses you are assured of the latter. Over one hundred BLISS Presses are operating in the plant where this photograph was taken.

BLISS on your machinery is more than a name, it's a guarantee.

REGO "Little Six"—$75.00

Complete, Portable, Standard Welding Equipment

THE REGO "Little Six" is the answer to the demand for a small but complete **high quality welding outfit** for garage and repair shop trade. It is called the REGO "Little Six" because the man who owns one can perform the six most important types of repair work. They are as follows: Welding, Cutting, Brazing, Lead Burning, Radiator Repairing and Decarboning. When used for welding the standard REGO M T welding torch equipped with three copper one-piece tips is used. This torch is suitable for all ordinary repair work, and

WILL NOT FLASH BACK

By changing tips, all the other operations already mentioned can be performed.

Standard REGO quality exists in every element of the Rego "Little Six" Outfit. Oxygen and acetylene regulators, hose, wrenches, spectacles, spark lighter and an instruction book that tells you how, all packed in an attractive carrying case, make Rego "Little Six" the most complete, high grade, small outfit ever offered to the repair trade. Price $75.00.

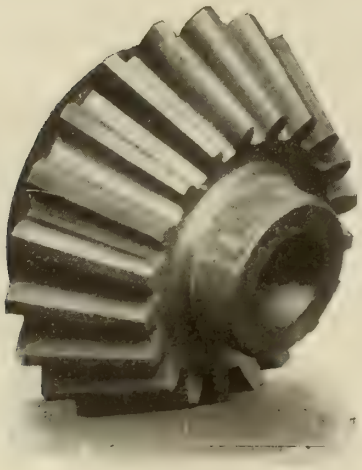
"FUSEON"

A new and better Metallic Flux for repairing water jackets and scored cylinders. You can secure the complete outfit with tools at the moderate price of $25.00.

See this equipment at the Toronto Exhibition in the Machinery Hall

Carter Welding Co., 165 Adelaide St., W. TORONTO, ONT.

Bevel Gears



Teeth Planed Theoretically Correct

Gear Data for Your Notebook

Cut this out---More coming later.

Bevel Gears—Rules and Definitions from
HAMILTON GEAR and MACHINE CO., TORONTO.

Relations of Pitch Diameter, Pitch of Teeth and Number of Teeth same as for Spur Gears.

Outside Diameter is Pitch Diameter added to Diametral Increment. This latter may be got from table (to follow) or worked out thus:

Diametral Increment equals double the cosine of pitch angle provided by the diametral pitch. Figure separately for gear and for pinion.

Pitch Angle is found from a table of Tangents. The number of teeth in a gear (or pinion) divided by the number of teeth in its mate gives the Tangent of the Pitch Angle. Face Angle is sum of Pitch Angle and Addendum Angle. Addendum Angle is found from table of Tangents. Twice the sine of pitch angle divided by the number of teeth gives the Tangent of Addendum Angle.

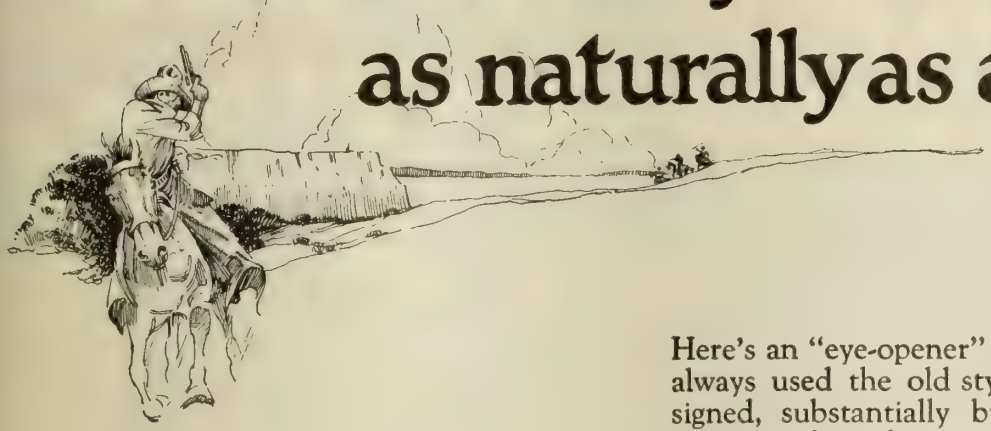
Balances in your hand as naturally as a Colt .45



Here's an "eye-opener" for the man who has always used the old style frame. A well designed, substantially built hack saw frame has a perfect "hang"—takes any length of blade from 8 to 12 inches and can be set to cut in four directions without removing the wing nut. A constant tension on the bolts holding the blade and a positive adjustment on the tubular back saves cuss words and much valuable time when changing blades. Hard rubber checked handle and stream line design. A Hack Saw Frame you will always swear *by*—never *at*.

Ask for *Starrett Pistol Grip Adjustable Hack Saw Frame No. 169.* You can get it at almost any hardware store.

BROWN & SHARPE VERTICAL SPINDLE MILLING MACHINES

For all types of milling, from Tool Work to Production Jobs

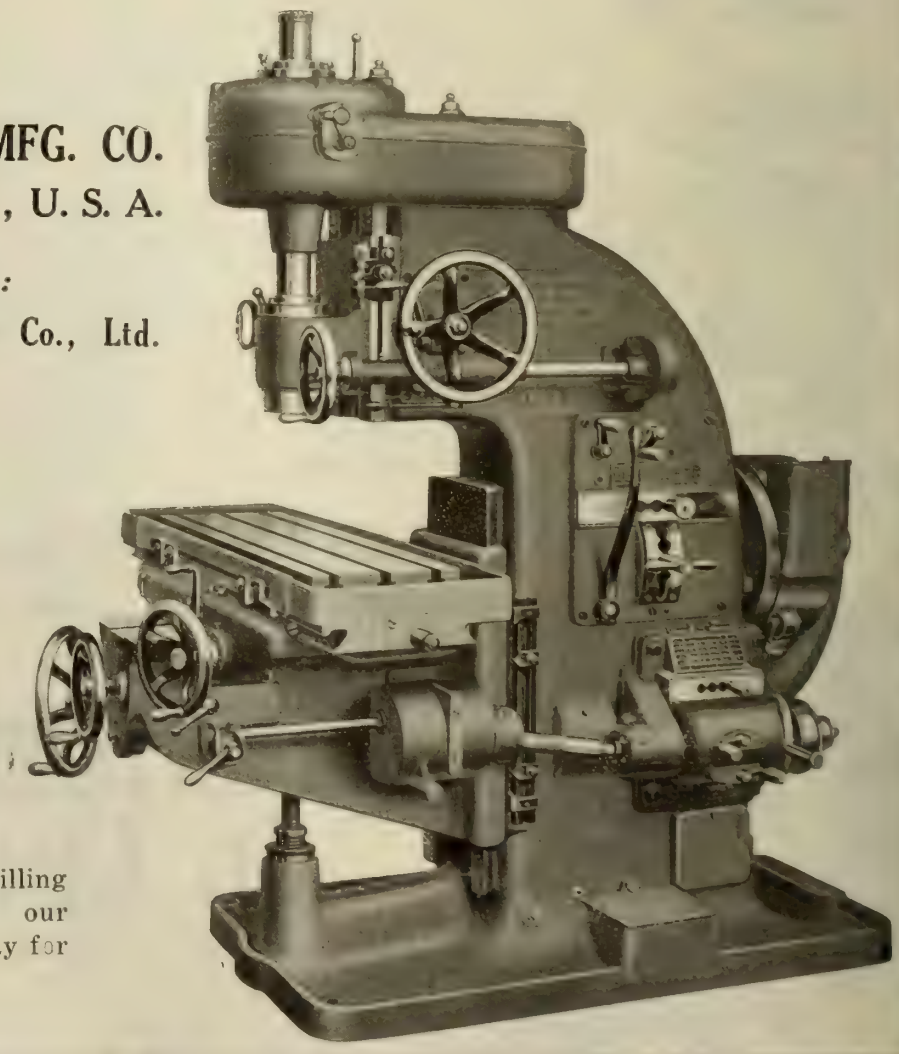
By using large, inserted tooth face mills these machines will mill a broad, even surface to a finish as accurate and smooth as can be desired. A single cut at one pass of the table removes more material than can be planed off in a much greater time. For die sinking and similar accurate work these Vertical Spindle Machines are preferable because of their accuracy and facility of control.

For milling or drilling to an accurate depth the vertical movement of the spindle head can be regulated by a micrometer stop. A reversing mechanism incorporated in the spindle drive enables the spindle to be run in the correct direction for drilling and permits the use of either right or left hand mills.

Ask for Specification Sheets giving further details

BROWN & SHARPE MFG. CO.
PROVIDENCE, R.I., U. S. A.

Canadian Representative :
Canadian Fairbanks-Morse Co., Ltd.



A SUGGESTION

The adaptability of this machine to a wide variety of work can be greatly increased by the use of a circular milling attachment, offering many possibilities such as continuous circular milling.

Four sizes of this type of milling machine are described in our General Catalog. Write to-day for a copy of Catalog No. 137.

If interested tear out this page and place with letters to be answered.

CANADIAN MACHINERY
AND
MANUFACTURING NEWS

VOL. XXXVII, No. 8 AUGUST 24, 1922

Some Interesting Examples of Production Drilling

Keeping Down the Labor Cost—Smoothness of Operations Essential—Special Work Holding Fixtures—Maintaining Alignment of Holes—Multiple Sprindle Drilling

IN THE machining of parts for mechanical equipment the drilling of holes assumes a prominent place in the scheme of production. It is the practice today to utilize a tool to its full capacity in order to keep the labor cost down to a minimum. Under the old system, where each individual hole in a piece of work had to be laid off and drilled separately, the labor cost was a very large item and the same methods would be almost prohibitive at the present time. The development of high speed steels and the improvements in machines to meet the new requirements has resulted in stepping up production to a point not even dreamed of a generation ago. In the early days of the drilling machines the general use of the tool for any other purpose than drilling holes was seldom thought of and less frequently practised. To-day, the drill press has become almost a universal machine tool that can handle a wide range of drilling, reaming, tapping and boring operations.

To get the best results out of any drilling machine it is necessary that smoothness of operations be the dominating features. The movements of the spindle and the feeds should remain uniform when cutting. When the feed is intermittent and irregular, owing to unnecessary friction and vibration, undue shocks are transmitted to the drill point and very often breakage results. Back lash in the driving gears and spindle should be kept as low as possible. Special attention should be given to the cutting points of drills to minimize the thrust that comes on the spindle bearing. This is particularly true in the case of multiple drilling, as it is desirable to maintain a uniform pressure on all spindles.

Use of Special Fixtures

When parts are manufactured in sufficient quantities to call for the undivided attention of one machine or set of tools for a comparatively long period, it is almost imperative that suitable jigs and fixtures be designed for holding the work while the machining operations are being performed. The use of high speed steel for cutting, and the rigid construction of tool equipment, has reduced the time required for the actual cutting operations to such an extent that quantity production at the present time is more a question of rapid handling and setting of the work than cutting down the time of tooling. On account of the irregular shapes of many component parts of mechanical appliances it would be very difficult, if not economically impossible to perform the necessary machining details without the use of supporting fixtures.

The imperative need of standardization and interchangeablity in present-day manufacturing, aside from the demand for increased output, is another reason why adequate shop facilities are necessary for assuring uniform and accurate product. These are essential requirements in all modern production schemes.

Handling Work Speedily

As the handling of the work is a very vital factor in the problem of quantity and quality production, the feature of speed in the manipulation of a work holding fixture is extremely important. Next to the accuracy of a jig the convenience of its operation should receive careful consideration, as the speed at which the work can be located and removed from position is the key of successful production. Whenever possible it is advisable to construct a fixture so that as many as possible of the drilling operations can be performed at the one setting of the work. This insures great-

Illustrations through the courtesy of the Tool-Burt Co., and the Bausch Machine Tool Co.

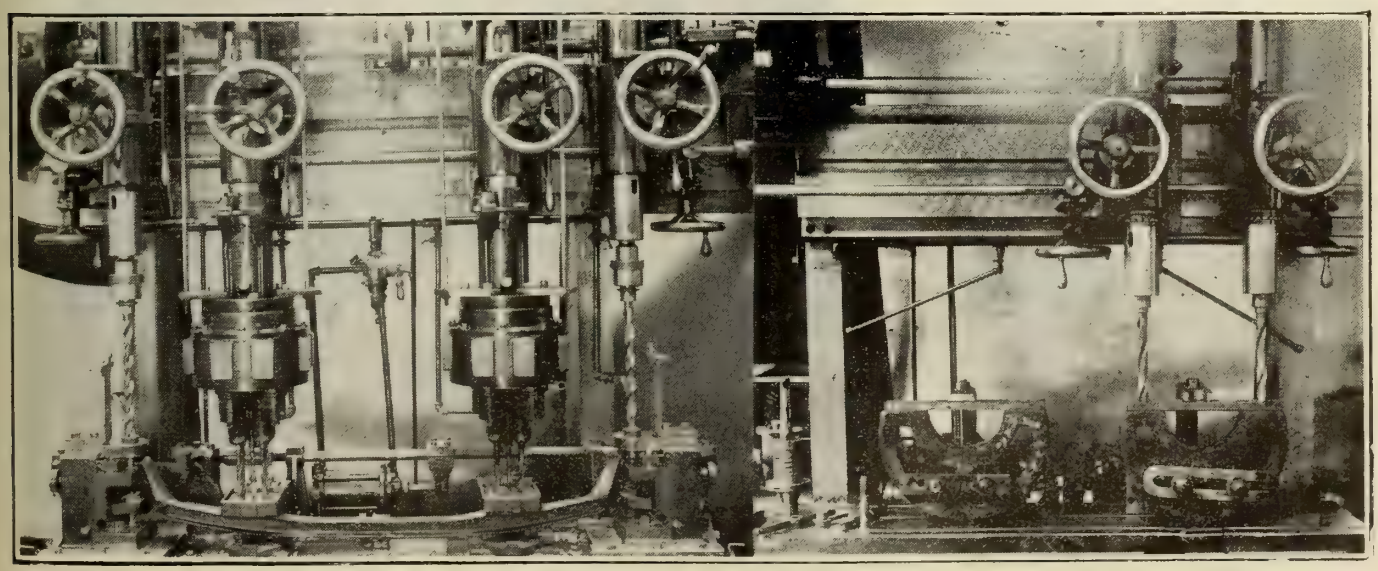


Fig. 1.—Left: Four-spindle machine drilling automobile front axles. Fig. 2.—Right: Drilling eccentric sheaves on two spindle machine.

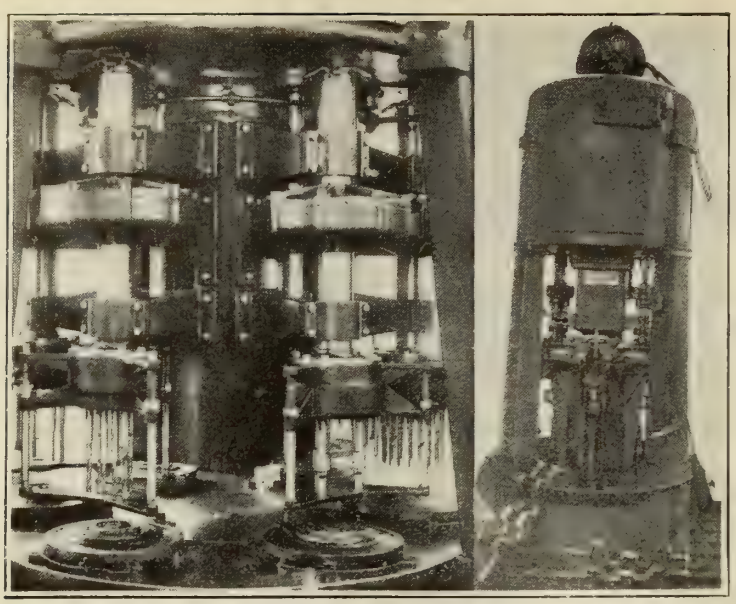

Fig. 3.—Six-station semi-automatic machine drilling automotive fly wheels.
Fig. 4.—Drilling and reaming holes in crank shaft flange.

er output and accurate alignment of the different holes. When it is necessary to change from one fixture to another to perform successive operations the same locating surfaces should be utilized in each fixture.

Multiple Drilling

When a number of holes are to be drilled in a piece of work and the quantity makes it permissible it is good practice to drill several or all of the holes simultaneously by means of multiple spindle machines. An operation of this kind is shown in Fig. 3. This illustrates a six-station semi-automatic machine designed for drilling, reaming, counterboring and end milling all holes in an automobile fly wheel. The production figures on this work are one complete wheel in 58 seconds with one operator. Fig. 4 illustrates a similar machine adapted for drilling and reaming six holes in the flange of a crank shaft. The production time with one operator on this machine is approximately 70 shafts per hour.

When it is desired to drill two or more holes at fixed centres in the one piece of work, or where two similar parts may be drilled simultaneously, the multiple spindle machine proves ideal in performing the necessary functions. An operation of this character is shown in Fig. 1. This shows a four-spindle independent feed drilling machine working on automobile front axles.

The centre heads are regular No. 4 independent heads fitted with five spindle adjustable auxiliary drill heads for spring pad holes. The end heads are regular No. 17 heads with the exception that they are fitted with hand facing attachment through bevel gears, this device being operated by a handwheel shown in a vertical position on the outside of each head; these head spindles are also fitted with ring operated quick change collets making it possible to change from drills to reamers without stopping spindle.

In loading this fixture the two end clamping slides are brought in place and as they are equalized the axle is centered accurately endwise and the V jaws provided in these slides also bring the axle up central sidewise; this will mean that irrespective of the amount of shrinkage variations in the axle forgings the king bolt holes will in all cases be drilled central with the king bosses; these clamping slides are operated by means of an air cylinder and the axle is clamped securely and quickly by this method. The small lugs at the top of the angle plates on each slide are used for spotting the end spindles so as to bring each spindle into alignment with the centre of the drill guide bushing. A production of 12 front axles per hour completely drilled and reamed is obtained.

Eccentric Sheaves

The advantages of this machine on front axle drilling work, connecting rod drilling and other automotive production operations, is apparent. This class of machine is also widely used for railroad shop work. Fig. 2 illustrates the drilling and tapping of two eccentric sheaves. In this instance it will be noted that the two sheaf sections are clamped to a common angle plate the vertical face of which is in the same plane as the cross slide of the drilling machine. The two drill spindles move in unison from one position to the other so that the same centre distance is maintained for all pairs of holes. While drilling is being performed on one piece the other is dismounted and a new one placed in position.

The Bausch Machine Tool Co. make a four-head horizontal drilling machine especially adapted for drilling all the holes simultaneously in automobile transmission cases. All spindles in the heads are driven from one motor shaft, the motor being located at one end of the machine. Special facilities are provided for drilling angular holes.

Drilling Harvester Parts

An interesting drilling operation is shown in Fig. 5. This illustrates the drilling of twelve holes in long pieces of pipe used in connection with harvesting machinery. The drill press is equipped with individual heads so that the spacing of holes can be varied at will. The work holding fixture is semi-automatic; in operation a movement of the lever A ejects the finished work at the same time moving the waiting pipe B into drilling position beneath the drill jig bushings, the spindles running continuously.

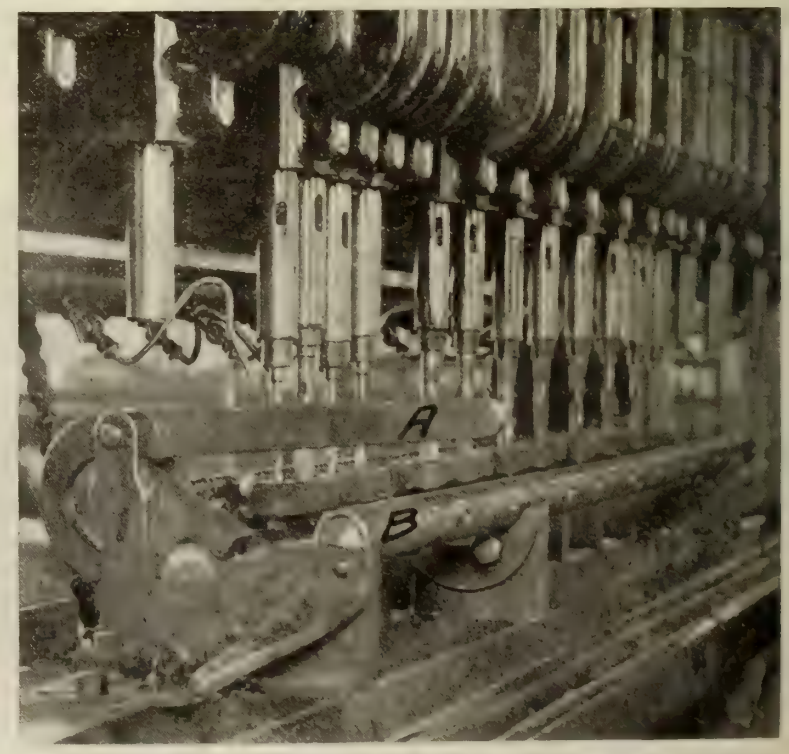

Fig. 5.—Drilling holes in pipes for harvesting machines.

Predicts Upswing in Machine Tool Markets

Dealers Optimistic as to Fall Business—Better Movement Reported in Some Quarters—DeBrul's Conviction That February and March Will See Return of Activity—Bases Observation on Pig Iron Production—Seven Year Period Between Depressions

F. F. BARBER, of F. F. Barber Machinery C., Toronto:—"Demand for machinery continues to be more or less spasmodic, but occasionally there are bright spots which encourage the conviction that things are getting better. We look for marked improvement next season."

J. C. Blair of Alfred Herbert, Limited, Toronto:—"It is encouraging that the Canadian machinery market, passing through a somewhat difficult period, is showing signs of betterment. Some machinery is being bought and as is generally the case in such movements, much of the business is coming from smaller manufacturers who are in a position to adapt their plants more easily to the demands of the occasion. I think we may now confidently expect a steady trend to more favorable conditions."

John Ferguson, Toronto office, John Bertram & Sons Co., Dundas, Ont.:—"For heavy equipment, such as we manufacture, there appears to be a better feeling in the market. Some machinery is moving, but you must consider that the month of August is generally dull in all departments. It is my opinion that the coming fall will see marked improvement."

F. W. Evans, Canadian Fairbanks-Morse Co., Toronto:—"Having concluded a survey of some of the more important cities and towns in Ontario, I will say there is every reason for optimism. The general tone is better, and while the demand for machinery is, of course, not what it should be, there is encouragement for aggressive work. Business in supplies maintains a gratifying level."

Wm. Garlock, Garlock Machinery, Limited, Toronto:—"The best that can be said is that the sun is shining in spots. It is a difficult time of year to pass decision upon conditions as a whole. We are all looking forward to much better business this fall. If it doesn't come then, why we will look forward to January, February and March. Hope springs eternal and I will agree that this is the time for optimism. The future looks bright and in the meantime we are all getting business, especially in the wood-working department."

T. A. Hollinrake, A. R. Williams Machinery Co., Toronto:—"Apart altogether from any sign or indication upon which to dope out the actual return of prosperity, my practical experience is that it is on the way. Machinery orders being received indicate that the country, industrially, is feeling better. When the movement may reach the peak, I cannot venture an opinion. Business is moving in the right direction."

T. H. Watson, president Canada Machinery Corporation, Galt.—"In my opinion, Mr. DuBrul's prediction that February and March next should see a return of activity in the machine tool business, sizes up the situation correctly. Everybody is ready to go. Crop prospects are favorable and that means much. As soon as present industrial troubles are washed out, industry and business generally should go ahead. I have just returned from the Maritime Provinces and there is great optimism there. All signs are encouraging."

H. W. Petrie, of H. W. Petrie, Limited, Toronto:—"Such conditions as these through which we are passing are, in my experience of 51 years in the machinery business, but resting points to prepare industry and business generally for problems of the future. I think I may say that every seven years, on the average, there have been recurrences of good and poor business conditions, and I have observed that almost every recovery is marked, first, by activity in the building industry. A machinery builder would, of course, be more inclined to regard movements in pig or steel. But the great point about it is that it always comes back, and I think we may safely say that it is now on the way."

There is remarkable unanimity in the foregoing statements with reference to the future of the machine tool market. They indicate that the optimistic period in the cycle has arrived. Anticipation is taking the place of apprehension, and with a future that looks well, and promises much, the long awaited upswing will gradually work its way into consideration. There is some fine philosophy in the observation of H. W. Petrie to the effect that "prosperity has always returned," and that these slumps, "heart breaking" as they may be to some and disastrous as they are to others, seem but stages when industry may pause temporarily to fit itself for better work, and broader perspective, if not for more thorough consideration of and adaptation to new or changing conditions. Even Babson, economist and statistician, states in a recent letter, that "for the first time in over two years he felt justified in talking optimism. From now on we shall be on the home stretch. We have reached the turning point in the business outlook."

Upswing Early in 1923

That the turn has been made and that an exhilarating change for the better is approaching, is the keynote of the August letter of E. F. DuBrul, Cincinnati, general manager of the National Machine Tool Builders' Association. As a close student of cycles and their attendant influences and results, Mr. DuBrul's opinions carry much weight in the industry which he represents. He considers the situation as affected by seven factors, namely, demand, capital, labor, material, fuel, transportation and equipment. In his summary it will be noticed that he adopts, as a reliable guide, the movement in pig iron and shows that machine tool demand develops its best stride some twenty months after low point of production is passed. On this basis, activity may be expected by February or March next. The summary, which, it must be remembered, comes from the heart of the American machine tool industry, follows:

Demand.—Now is the time to watch the signs. In previous cycles pig iron production generally reached the peak of the preceding cycle about twenty months after the low point, and not much before that time did the demand for machine tools become brisk. According to this past history, demand for machine tools may be expected to be active by February or March of 1923.

Capital.—Funds should be ample for the next year or two. The facilities for inflation are greater to-day than they were in 1919. The present cycle may easily develop into a relatively short period of sharp activity, with high prices and low production.

Labor.—Labor shortage is now apparent. Short labor supply creates demand for machinery of all kinds, and increases the activity of management in devising cost cutting plans, including labor-saving machines. The machine builder faces high costs, due to high wages and the necessity of training new crews.

Material.—The coal and railroad strikes are causing restriction in the supply of material. Prices of iron and steel continue to increase. All signs point to a continued upward movement in the demand.

Fuel.—Continuance of the coal strike coupled with the railroad strike make very short supply of fuel. In spite of efforts at stabilization, prices have gone up and will surely be high in the fall

Transportation.—The shopmen's strike is curtailing production in many lines. There will undoubtedly be a car shortage this fall, with delayed shipments and a repetition of the transportation demoralization that we had early in 1920. This will make for high prices generally.

Equipment.—The equipment factor is not limiting production at this time. However, with the growing shortage of

labor, the equipment factor will begin to become stronger each month, and should be reflected in machine tool orders.

Dealing with phases of demand, Mr. DuBrul continues: The whole world has been very sick, economically speaking. The convalescence takes time and cannot be hurried. General business is still very far below normal, but the period of optimism is under way.

Students of the cycle well know the optimistic and pessimistic stages, and they well know that when in the progress of the business cycle prices are going up, sellers and buyers are found co-operating to put them up further, so also when they are going down there is a similar co-operation.

All indexes of demand, price and production, indicate that the present cycle is definitely on the upswing and we have entered the period of optimism. Certain effects of the labor, fuel and transportation factors now combine to make higher prices, and as usual buying will be stimulated because it is merely human to buy on a rising market instead of on a dead market.

Demand for Machine Tools

Machine tool demand responds to the upswing considerably later than other demand, so that the concerns that have been able to survive the "heart-breaking" slump ought soon be in a position to begin the exhilarating rise on the upward swing.

In anticipation of the rise it is well for members of the association to review their experiences in some previous depression, notably 1904, 1908, and 1911.

1904.—The low point in pig iron production was reached in December, 1903. Machine tool demand did not become brisk until July, 1905—about twenty months after, when pig iron production got well past its previous peak.

1908.—The low point of pig iron production was reached in January, 1908. It did not reach its previous peak until September, 1909, or about twenty months after the low point was passed. The machine tool builders did not reach full activity until about October, 1909.

1911.—The low point of pig iron production was January, 1911. It did not reach the previous peak until October, 1912, or twenty-one months after the low point. Machine tool demand did not fully occupy the plants until about that time.

1914.—A low point was reached in pig iron production in January, 1914, but when the war in Europe broke out this cycle was complicated, and a still lower point was reached in December of 1914. Curiously enough, however, the previous peak was passed in October, 1915, again about twenty months after the January, 1914, low point.

If the present cycle runs true to form, then the low point having been reached in July, 1921, the previous peaks attained during the war would be reached somewhere near February or March of 1923, and we could expect the machine tool business to be very active by that time.

War Accentuated Cycle

It is interesting to note that the war merely accentuated the cycles, and that the seven year interval between depressions came on in 1921, almost according to schedule. The machine tool builder can get plenty of warning of activity, and can make his preparations accordingly if he will watch the signs. The indexes of capital accumulation have always checked in closely enough for all practical purposes in making forecasts in the machine tool business. Although the world's situation as to capital, and the labor situation in the United States, coupled with political movements, make one more cautious, it looks as though humanity is going to run true to form; perhaps a little slow, but finally getting around in about the same way as usual.

Close attention to the signs of the times for the next few months ought to be very well rewarded. The chances are that we may have a relatively short, sharp activity, somewhat inflationary in its nature, and for that reason one that must be watched closely if this industry is not to again get stuck with a lot of inventory, accumulated at high costs just as the demand is sliding out from under it. Conditions being created by the fuel, labor and transportation factors seem to be very likely to bring this sort of cycle about.

Labor and Material

Mr. DuBrul adds:—"The labor situation has a double interest for the machine tool builder. On one hand, demand for his product must soon become evident, and as shown by our barometer figures this demand is now on the way. On the other hand, the scarcity of labor and the high cost that the machine tool builder is bound to face, due to high wages and the necessity of training a whole new crew, makes the labor factor a very important one for the machine tool builder to take count of, in making his price.

"The railroad and coal strikes, by decreasing production, are sure to increase prices just as in 1919. A period of rising prices could develop into a period of inflation based on high profits and fairly low production, rather than a period of prosperity based on heavy production and low profits.

"All indications are that when the strikes are over there will be a continued upward movement in the demand for iron and steel, and perhaps also in the price. It does not pay to become panicky and to throw all the orders into the market at one time, but a forehanded man will make reasonable provisions with responsible suppliers who will meet their contracts. There will no doubt be a pressure of demand as a result of the supply being shortened by the strike, and the longer these strikes last the greater will be that pressure.

"The shortage of industrial equipment is not yet a marked limitation on production in any line of business at this time. However, with the growing shortage of labor relative to general demand, the demand for high production equipment will come on stronger each month and will be reflected in machine tool orders."

MACHINISTS IN ANNUAL PICNIC

There was a record attendance of about one thousand at the annual picnic of the International Association of Machinists, district No. 46, in High Park, Toronto, Aug. 12. Five lodges were represented namely, Leaside, No. 1252; Junction, No. 371; Toronto, (contract men), No. 235; Brassworkers, No. 1,301; and automobile lodge, No. 772. The program of sports comprised events for the children as well as grown-ups, and there was a baby show in which the entries formed a particularly fine representation of oncoming Canadians. Joe Bannon, C. P. R. roundhouse machinist, Lambton Mills, carried off a special cash prize as the member having the largest family on the grounds. When the Bannons mustered ten on this auspicious occasion they stifled all competition. No mean task was assigned Mrs. J. P. Crompton and Mrs. Wm. Williamson when they took charge of the refreshments. Fifteen hundred ice cream cones, 15 gallons of ice cream, 24 gallons of tea and 18 gallons of milk were accounted for, besides much else, and after that the picnickers were photographed, forming a happy, prosperous looking group. During the afternoon, the labor situation was discussed by Harry Harper, Toronto, and H. Kerwin, Montreal grand lodge representatives; R. J. Tallon, president of division No. 4 railway employees, Montreal, and Mrs Singer, national vice-president, Ladies' Auxiliary, Toronto

DANGER IN PULVERISED COAL

Careless handling of pulverised coal has caused a number of fires and explosions, and it is desirable that where pulverising is adopted the unit system should have preference. Pulverised coal in bulk is not particularly dangerous, but hazard occurs when the dust is raised in the form of a cloud. In the unit system the fuel is pulverised at or near the point of use and delivered from the pulveriser in a stream of air directly into the furnace by means of a fan which is a part of the pulveriser. This system eliminates the dangers incidental to a central system, involving storage, piping, etc. A great source of trouble to users of pulverised coal has been due to fires in storage bins. There can be but little doubt that spontaneous combustion plays a large part in the origin of these fires. All storage bins and furnace bins containing pulverised coal should be as far as consistent with operating requirements from furnaces and away from open lights and flames. Motors of the non-sparking type, preferably squirrel cage motors, are the nearest explosion-proof motors now available. All machinery should be thoroughly grounded to prevent sparks due to static electricity.

Efficiency of Various Types of Belts and Lacings

Constructional Features of Different Materials—Choice of Belts for Power Transmission—Conditions Often the Governing Factor—Advantages of Steel Belt Lacing With Alligator Hide Pin

THE purpose of a belt drive is to carry a certain amount of power from one pulley to another. Therefore the problem that confronts the belt user is that of determining the kind of belt to purchase in order to secure the desired results. The amount of power transmitted will depend on the velocity at which the belt travels, the tension under which it is placed on the pulleys, the arc of the smaller pulley with which the belt is in contact and conditions under which the belt is used. There are several different types of belts, all of which have considerable merit. Some are more adaptable to certain conditions than others and considerable care should be exercised in making a choice. Regardless of the kind of belting to be purchased it is essential that certain facts be known before an intelligent decision on any belting problem can be reached.

It is always advisable to supply the manufacturers from whom belting is purchased with complete details and allow them to advise you from the viewpoint of greater and more practical experience. No thoroughly accurate decision bearing on the purchase and use of belting can be arrived at without the following information:

(1) Horse power to be transmitted: (a) average; (b) least; (c) most. (2) Diameter of driving pulley. (3) Diameter of driven pulley. (4) Number of revolutions per minute made by one of them. State which one. (5) Distance between pulley centers. (6) Whether drive is vertical or horizontal. (7) Whether the tight side runs on top or underneath. (8) Operating conditions such as dampness, fumes, flying dirt, changes from light to heavy load; high speed over small pulleys; running at quarter twist; use of idlers, mule pulleys and stepped or flanged pulleys.

Compiled from material supplied through courtesy of the Flexible Steel Lacing Co., Chicago, Ill.

However, certain types and sizes of belts have been proven thoroughly satisfactory and are known to be standard for many uses. Belting salesmen and many dealers can tell you accurately what these standards are, based on your requirements of horse power, use, size of pulleys and working conditions. Many belting salesmen will be found to have an excellent knowledge of belting installations, even on the most technical and unusual points and they will gladly work out knotty problems with you in connection with your purchases of the beltings they recommend. It is confusing at times to learn from salesmen of different kinds of belts that each type seems to fit your requirements perfectly. But in many cases the interchange of types is possible. Your guide as to the class of belt will have to be founded upon a knowledge of good usage, of cost per year and of working conditions. It is as a guide to a good choice that the following information has been prepared.

Fabric Belts

Fabric belts can be divided into three general classes. (a) Solid woven cotton, camel's hair, or other fibrous material (usually impregnated with a waterproofing compound). (b) Stitched canvas. (c) Rubber or balata which are composed of several plies of cotton duck cemented or vulcanized together with the tropical gums, giving them their name. There are numerous plies, weights and forms of weaving and stitching. Several varieties of American and imported cotton fibres are also used in the fabric base.

Cotton is the material of general use in making woven and stitched belts. There are two general methods used in making. The more common is the combining of several layers or plies of cotton duck. These plies are sewed or stitched in various patterns to increase the tensile strength and prevent excessive stretching of the material. Various weights of duck are used and in purchasing it is advisable to know exactly the weight of the material, the kind of cotton used and the methods of weaving. Even then the specifications may be so confusing that the best method is to place dependance on the recommendations of a manufacturer whose name and product are well known and of proper worth. The solid woven belt is produced from a special yarn of cotton or other fibre woven into solid belt in somewhat the same manner as a lamp wick. The different makes of this type vary considerably in the weave and method of manufacture, but all possess a homogeneous body produced in widths and weights proportioned to the service required. In both methods of manufacture the material is specially treated to withstand friction. dirt, atmospheric conditions, etc.

Rubber Belts

The construction of rubber belting consists of a backbone of cotton duck which is specially treated with rubber compound. Crude rubber is obtained from the Hevea tree, which grows in nearly all tropical countries. It yields a milk-like fluid that thickens and becomes dark upon contact with the air. The rubber gatherer prepares the fluid for market by pouring it over a stick and turning it around in the thick yellow smoke of burning palm nuts. This smoking process imparts a tough, tenacious quality to the rubber. As each layer hardens more fluid is added until the ball is about twelve inches in diameter. The balls are then split for shipment. Methods of preparing the rubber compound and applying it to the duck

base differ in method but the principle is generally the same.

The duck is inspected and tested for imperfections. All moisture is removed. The compound is applied and forced into the plies by pressure. The whole is then vulcanized under terrific pressure which removes all superfluous stretch and unites the rubber and duck into one inseparable body. Rubber belting is made in both red and gray colors.

Balata Belts

Balata belting has a canvas base or backbone similar to rubber belting. Balata is a vegetable gum that comes from the milk of a tree which grows in the Guianas.

The process of manufacture differs somewhat from rubber belting. The fabric is thoroughly impregnated with Balata gum. The outer surface is finished off with a thin coating to give it a finished appearance. The whole is welded into solidity under pressure, although it is not vulcanized in the manner of rubber belting. This type of belting is satisfactory for general transmission service, other than where extreme heat prevails.

Rope Belts

Rope belts are more extensively used in Europe than in this country. The English system employs a single grooved drive pulley from which several parallel rope belts distribute power to several places. The English multiple rope method employs several parallel ropes over grooved pulleys for main driving power. In contrast to the English multiple system is the American single rope belt. The rope is carried around the grooved pulleys as many times as necessary to gain the desired power. From the last groove in the driven pulley the rope is carried by an idler back to the starting groove in the driving pulley. In this way a continuous single rope drive is secured. Among the advantages offered by rope belts is their economical installation and their ability to transmit power to considerable distance.

Metal Belts

Plain steel band belts are used to some extent in Europe but are not employed as yet in this country, except possibly in very few isolated cases. Their principal advantages are in their light weight, their being impervious to dampness, and the consequent high speed at which they can run without any noticeable effect from centrifugal action. Belts of this type commonly run from 0.008 to 0.036 inch in thickness and in width from ⅞ in. to 8 in., and are operated at speeds up to 10,000 feet per minute.

Metal chain drives are made of flat steel links joined by pins. They are adaptable for high speed work and heavy loads and can be used to good advantage where pulleys are close together.

Leather Belting

This type of belting is efficient, and in standard grades gives long service. The wearing qualities and slight attention required have made its use general under the conditions to which it is suited. The best leather belts are from selected hides of mature steers killed in the fall. The hides of old animals have lost some degree of their flexibility, and the immature have not gained their greatest strength. For the best wide belts only a center back strip, 30 inches wide and 50 inches long, is used. As the distance from the spine increases, the stretching quality of the belting varies. For narrow belts strips cut equally distant from the spine or either side and spliced together are used, this making a belt that stretches evenly and runs straight over the pulleys. Oak tanned leather is the type most used in general work. It is light in color and firm in texture.

The best oak tanned leather is "currried" after tanning, the processing involving the working in of oil and tallow. This gives it greater flexibility and a soft finish. Ordinary oak tanned belting is not at its best when exposed to certain conditions, such as the action of water, steam, oil, heat, chemical fumes, etc., for work under these conditions leather belts should be specially finished. Chrome leather belting is one of the best for special purposes. Chrome tanning imparts qualities to the leather which enable it to be used under the most severe conditions such as excessive heat, steam, etc. Single leather belting consists of one thickness. Double belting is composed of two thicknesses of leather; the strips being cemented together. Heavier belts are sometimes made for special purposes but can only be used to advantage over extra large pulleys.

Direction to Run Belts

In cases where belts are spliced the belts should be run in such a direction that the thin edge of the splice on the inside of the belt should be the first part of the splice to run over the pulley.

There is considerable difference of opinion among authorities on this point and we have given the rule in most favored use. Several well known authorities assert that the reverse is preferable. The disagreement is founded on the action of the air or of the pulley surface in turning back the lap and thus causing the splice to break down.

In splicing double leather belts arrange laps like the above illustration. The thin edge of the laps on both outside and inside of belt should point away from the direction of running.

Side to Run Next to Pulley

The general practice in this country and the one recommended by the foremost makers of leather belting, is to run the hair side next to the pulley since this gives the greatest length of service. On the other hand the general European practice is to run the belt with the flesh side to the pulleys, because this side grips and has better cohesion than the hair side. But belting run in this manner has a tendency to crack and

The metal hinge open and closed.

split as the greatest strain comes on the close grained hair side.

Belts and Their Uses

Leather belts will render excellent service for practically every power transmission purpose except when exposed to the action of water, steam, oil, heat and chemical fumes — but action of these elements can be largely overcome by special processes of preparation if the manufacturer is supplied with information regarding these conditions.

Woven, stitched canvas and other fabric belting gives satisfactory results where exposed to moisture, or the action of weather, or where there is considerable grit and dirt. It is used extensively in elevating and conveying operations. The initial cost is comparatively low. Although this type of belt has a greater tendency to stretch than leather, constant improvements in construction are resulting in good general purpose belting that has many friends.

Rubber belting is becoming steadily more popular. Its extreme flexibility, excellent pulley grip and ability to withstand moisture and climatic conditions are its most desirable features. It is used for elevating and conveying purposes; in paper mills, brick yards and other industries where unusual conditions are encountered, as well as for general power transmission.

Balata belting has advantages similar to rubber belting and can be used under the same general transmission conditions excepting where exposed to extreme heat.

Care of Belts

Belting is one of the greatest single expense items in a belt-driven plant. To reduce this item to the lowest possible level, belts should have systematic inspection and intelligent care. **Keep belts clean.** Where exposed to dirt or dust, rub them occasionally with waste or some coarse fabric. Never let mineral oil come in contact with any kind of a belt. If oil or grease does reach a belt it should be removed at once with gasoline after which a dressing adapted to the belt should be applied to give the necessary elasticity. Where belts have become dry and hard or have stretched so as to allow excessive slippage an application of good belt dressing will help considerably.

Belt Dressing

It is always best to use a belt dressing recommended by the manufacturer of the belt on which it is to be used. We give below several short cuts to dressings which will be found satisfactory.

To clean and loosen leather belts use this dressing which is similar to that put on new belts by manufacturers.

Edible beef tallow .....2 pounds
Cod liver oil .....1 pound

Melt the tallow and allow it to cool slightly. Then add cod liver oil, stirring the mixture in one direction until cold. Apply in such quantities as the belt will absorb, using a light camel's hair brush. Neatsfoot oil improves the performance and durability of leather belting, but is injurious to rubber belting.

A few drops of castor oil judiciously used, will prove a good dressing on rubber belts.

Canvas belting can be kept in good working condition by the light application of castor or raw linseed oil at intervals. The cost of the amount of belt dressing used is small compared to the benefits to the belt. It is suggested that a dressing made or approved by your belt maker be kept on hand for regular use.

Factory Belt Room

Every establishment using considerable belting should maintain a separate room for belting repairs. It is a good policy to keep extra belting on hand for emergencies should a belt give out entirely.

Sooner or later every belt is bound to break. Usually the break occurs when it will cause the greatest loss of time, labor, material, production and expense. Various methods of making repairs have been evolved. Alligator steel belt lacing is adapted to all kinds of belting—leather, woven, cotton duck, camel's hair, rubber, balata—of every combination of thickness, width and length. It renders perfect service on all kinds of drives, whether open or serpentine—over any pulley or idler. In fact this lacing makes a perfect flat flexible joint that will go anywhere the rest of the belt goes. The joint is flat on both sides and sets flush with the surface of the belt. The double toothed jaw of the Alligator lacing grips the belt from both sides and clinches in such a manner as to secure a strong hold without weakening the belt. It is so constructed that the pull comes against the edge of the teeth—not the flat.

Only a Hammer Required

In a working time of only three minutes the average belt can be laced with this steel belt lacing. No tool but a hammer is required. No special skill or training is needed. Any one can repair a break in short order.

The double staggered teeth give extra strength to the joint. Notice how the long end teeth pierce the belt and are clinched tightly with the hammer. In damp or heavy work where other lacings pull out this steel belt lacing holds securely.

The short flexible joint insures smoothness of operation. One very important feature is the special steel rods with lugs spaced to correspond to sections in the lacing. Lugs hold them in place and oval faces form a frictionless "rocker" for the flexible joint.

The tensile strength of belting joints made with any size or kind of fastener or lacing will vary according to the kind of belt, higher results being developed with the same size of fastener or lacing on belts of firm structure as compared with those of poor quality.

TAKING THE PUNCH OUT OF SHELLS

A contract with the British Ministry of Munitions to break down all surplus ammunition in Great Britain has been undertaken by George Cohen Sons and Co. The amount to be thus disposed of is approximately 500,000 tons, and consists of all classes of material, including high-explosive shells from 15in., weighing three-quarters of a ton, down to the small pom-poms, weighing 1 lb., aerial bombs weighing 1600 lb., millions of hand grenades, and gas shells. All this ammunition has to be rendered innoxious; chemicals have to be recovered in some cases, and the steel shells have to be made absolutely free from chemicals and explosives, so as to make them suitable for the steel furnaces. Factories had to be built and equipped at Farlington, near Portsmouth; Gainsborough, Pembrey, Banbury and Creden Hill. At present, upwards of 3,000 men are employed on the work, and to date over 135,000 tons of ammunition has been completely broken down, and the material consumed by the steel works and brass foundries in the country. The Disposal and Liquidation Commission has now entrusted the firm with a further contract, and an arrangement has been made whereby it is to undertake the clearance of the whole of the empty shells and shrapnel which has been thrown up for disposal, also all the arisings from the Government depots during the next six months.

NEW RAILROAD CAR

The Great Eastern Railway of Great Britain announce that they are trying out on a branch line, a railway car so easily moved that its brakes must be kept in order to keep the wind from moving it along the tracks. The journals are fitted with a new type of ball bearing. Railroad engineers admit that it will be a great saver to power, but are not sure that it will be able to stand up against the hard usage to which it will be subjected in actual service. The bearing parts are constructed of steel hardened by a process discovered during the war.

Fine Demonstration and Display at Exhibition

Wide Range of Machine Tools, Equipment and Accessories Representing Great Variety of Industries—Rubber Goods Production Well Represented—Good Prospect for New Engineering Building—Project Well Received

EACH succeeding year, Canadian National Exhibition, which opens Saturday, August 26, attempts greater achievements not only in attendance, but in features that will still more intimately portray the agricultural, industrial and commercial growth of Canada. Each year brings closer a realization of the dream that engineering enterprises particularly in machinery and equipment of different kinds will have adequate housing accommodation and proper facilities for display. The plan of the exhibition board is to segregate industries to distinctive buildings, and many fine structures have been added within recent years. Thus the automotive industry occupies the Transportation building, and the display here will undoubtedly form one of the outstanding features of the big fair this year.

Plans have already been drawn up for an engineering building that will make old Machinery hall look like the York pioneers' cabin alongside a modern dwelling. Canadian Machinery gave a detailed description of this structure recently, and the illustration herewith is of the front elevation. The idea is to make each of these new buildings pay for itself by rental of space and a committee of manufacturers of which T. A. Hollinrake of the A. R. Williams Co., is chairman, has this department of the undertaking in hand. Already, quite a large amount of space has been contracted for. The new building will not be far from the eastern entrance to the Exhibition grounds, and is so planned as to give the best space, lighting and shipping facilities. The project is receiving enthusiastic support. All things being favorable the structure may be ready for 1923, but, in any event, not later than 1924.

This year's exhibits in Machinery hall and Industrial building of machinery and associated activities, constitute quite a representative display and there are many interesting demonstrations. Following are brief descriptions:

Anglo-Canadian Leather Co., 666 King St., W., Toronto, location Manufacturers building, represented by S. L. Lawther. Display of different grades of oak and hemlock sole leather and tap soles for shoe repair trade.

John Bertram and Sons Co., Ltd., and Pratt and Whitney Co. Ltd., Dundas, Ont., Toronto offices, 32 Front St., W. Represented by John Ferguson, T. Woods and A. Mover. Display in Machinery hall of machine tools and small tools such as reamers, cutters, taps and dies, comprising an extensive range.

Black Donald Graphite Co., Calabogie, Ont., location Machinery hall. Display of extensive range of graphite products for industrial purposes.

The Brown Boggs Co., Hamilton, location, Machinery Hall; display of tinsmiths' and sheet metal workers' tools and machinery presses, shears, etc. Represented by W. J. Graham, W. E. Blandford, A. B. Walker and F. L. Lavery.

Bond Engineering Works, foot of Cherry St., Toronto, represented by P. E. Thring; location, Machinery hall. This is an extensive display of Bond transmission equipment, featuring specially the Grundy flexible insulated coupling, together with truck castors of ball-bearing-swivel and other types. This exhibit emphasizes the various features of bond products that adapt them to a wide range of industrial purposes and includes various types of shaft hangers and bearings, pillow blocks, clamp boxes, floor stands, wall brackets, base plates and the Bond "spiro" compression coupling which is so constructed as to exert an enormous gripping power on the shaft plates and clamp couplings are also shown as well as a range of safety collars.

A prominent feature is the Grundy patent flexible coupling. The merit claimed for this equipment is based on the absence of rubber parts that disentegrate and there are no springs or screws to come loose. Of three parts entering its construction, two are metal flanges, and hence indestructible; the third part is a leather disc cemented and riveted, which, it is claimed, under normal conditions will last for years. This coupling is used wherever flexi-

Proposed engineering building to take place of old machinery hall at Toronto National Exhibition.

bility is required, while the leather disc serves as an effective non-conductor of electricity. This in many cases is very desirable. The coupling is necessarily of such accurate construction that each driving point of the flange bears uniformly on each lug. That is, each lug takes its proportion of the load instantly, so that it is thoroughly distributed and the bearing surface of the flange being so wide, there is no chance for the lugs to shear off or wear.

The Booth-Coulter Copper and Brass Co., 115 Sumach St., Toronto, location Industrial building, represented by A O. Wilson and F. P. Miller. Display of fire guns for automobiles and motor boats, brass and copper goods, brass castings, fire extinguishers and a new line of art brass goods.

The Canadian Hanson and Van Winkle Co., Morrow Ave., Toronto, location, booths 6 and 6A Industrial building. Represented by J. Elder, J. Acheson, Wm. Salmon and Wm. Whalen. Display of plating and polishing equipment including polishing wheels, buffs, buffing material, scratch brushes, Royal and Capital pickle salts cyanide, carbonate of copper and zinc, cyanide of sodium, anodes of nickel, copper, brass, bronze and zinc, also a full line of lackers and brushes and brooms for domestic use.

Clipper Belt Laces Co., Grand Rapids, Mich., location Machinery hall. Display of their various types and sizes of their belt-lacing equipment, also specimens of their work.

Cowan & Co., Galt, location Machinery Hall, represented by S. F. Barrows. Display of woodworking machinery as follows:

Power feed rip saw, 280, with variable feed; automatic knife grinder, 277, for grinding planer knives with water attachments; chain saw mortiser; belt sanding machine with rolling table, 319; vertical hollow chisel mortiser with power feed.

Crane Limited, 88 Terauley St., Toronto, location Process building, represented by E. J. Laidlaw, H. W. Ballis, J. H. Ryding and H. Tabbiner. Display of steam goods for power plants—valves, fittings, pipe bends, special flanges and other steam specialties.

Dominion Belting Company, Hamilton, location, Machinery Hall, represented by Mr. Kinrade. Display of Maple Leaf brand stitched cotton belting and belt dressing.

Dominion Rubber System, 1 Front St., E., Toronto, location Industrial & Transportation buildings. Display and demonstration in charge of J. H. Robertson and representative staff of thirty-five salesmen. Large exhibit in industrial section, demonstrating manufacture of commercial felt, rubber footwear and athletic goods, with several tableaux, having decorative background, illustrating rubber footwear styles. Exhibit also includes revolving pyramid displaying belting, hose and light mechanical goods and features, further a model shoe store. Motor car tire display in Transportation building.

Gutta Percha & Rubber, Limited, 47 Yonge St., Toronto. Locations, Industrial and Transportation buildings. Represented by traveling sales staff. Display in Industrial building of mechanical rubber goods—belting, hose, packing, mats and matting and folded rubber goods. There is also a display of rubber footwear, rubbers, athletic outing goods and heavy wear such as boots, etc., and Maltese Cross rubber heels. Transportation building has display of auto tires, tubes and accessories.

Dunlop Tire and Rubber Goods Co., Queen and Booth Aves., Toronto: location, Transportation and Industrial buildings, the former in charge of H. C. Austin, district manager; and the latter in charge of Leo Levy, assistant mechanical sales manager. Transportation display consists of tires, cord and fabric, giant pneumatics and solids for trucks, tubes and accessories. The exhibit features a mileage guessing contest, in which the central operation consists of two car wheels propelled by motor and with speedometer attachment. The wheels revolve on a surface and run for 12 hours daily. Prizes will be awarded for the 25 nearest correct guesses as to mileage covered by these wheels in the two weeks of the exhibition. The display in the Industrial building will consist of mechanical goods such as belting, hose, and the new flooring, rubberoleum, together with moulded goods, such as golf balls, etc.

The Elliott Machine Co., Belleville, location Machinery hall. Display of different types of portable woodworking machinery—planers, band saws, floor and drum sanders, scroll saws, etc.

Fisher Motor Co., Orillia, Industrial building, display of die castings, also accessories, and attachments for soda fountains and ice cream service.

Gurney Scale Co., Hamilton, location Industrial building. Display of range of heavy industrial scales for various purposes.

Ingersoll Machine & Tool Co., Ingersoll, Ont., location, Electrical building. Display of electric iron boards and equipment and also exhibit of small tools such as reamers, milling cutters, and specials.

International Nickel Co., of Canada, Limited, Harbor Commission Building, Toronto, location Industrial building, representative C. A. Richardson, sales engineer. Display of non-corrodible and rust-resisting qualities of Monel metal, as illustrated in meat slicers, water coolers, refrigerator parts, meter diaphragms, tea kettles, name plates, etc., also Monel metal castings as produced by St. Catharines Brass Works. Exhibit further includes nickel specimens in ingot and other forms.

International Business Machines Co., 300 Campbell Ave., Toronto; two exhibits located in Industrial building; represented by Allen Buddo. One exhibit consists of computing scales, bacon scales and meat slicers, cheese cutters, electric meat choppers, coffee mills and coffee roasters. The time recording machines department will be represented in an exclusive display by electric time systems, time recorders, job time recorders, elapsed time recorders, self-winding master clocks and secondary clocks.

Jones and Moon Electric Co., 296 Adelaide St., W., Toronto, location Machinery hall, represented by W. Dalton, displaying Century electric motors ranging in size from one-sixth to 60 horse power.

Lancashire Dynamo and Motor Co., 45 Niagara St., Toronto, location Machinery hall, represented by Albert Lloyd, display of standard electric motors and other electrical equipment.

L'Air Liquide Society, 16 Boler St., W., Toronto, location Machinery hall, represented by Andrew McDougall, R. Godfrey and L. Sykes. Exhibit and demonstration electric and oxy-acetylene welding and cutting apparatus. Demonstration of the use of special rods for electric welding.

D. K. McLaren, Limited, 194 King St., W., Toronto, location, Machinery hall, represented by W. S. Hamilton. Display of belting, extra C. leather and woven cotton; belt dressing, split pulleys, and a line of supplies for cotton and woollen mills, rope banding, spindle banding, picker leather, sticks, etc.

James Morrison Brass Co., Limited, 93 Adelaide St., W., Toronto, location Industrial building, represented by Arthur Betton, W. Dobbin, and J. Noble. Display of varied line of steam specialties, and standard brass goods, including boiler and engine mountings for stationary, marine and locomotive types; injectors, pressure recording gauges, engine clocks and counters and J. M. C. pressure reducing valves. The exhibit also features automatic cellar drainer and gas water heaters.

Moore Bros., 61 Nelson St., Toronto, location, Machinery hall, represented by W. F. Moore, showing two ball-bearing grain grinders such as used in shopping flour, feed and grist mills.

Northern Electric Co., Ltd., 131 Simcoe, St., Toronto, location, Industrial building, represented by B. L. Baulch, W. M. Woodward, W. Hollowell, and E. C. Coome. Display featuring telephone equipment for private automatic exchanges for industries and institutions such as hospitals. There will also be shown telephone apparatus for rural operating companies, magneto telephone equipment and fire alarm apparatus. Radio display at Prince George Hotel during exhibition.

Macauley Pope, 186 Bay St., Toronto, location, Machinery hall, represented by Macauley Pope, in a display of wire and

wire rope made by Wilkins Wire and Wire Ropes, Limited, England. Mr. Macauley states that this is the first time a British product of this kind has been shown at the exhibition. An interesting feature is a display of wire rope used on the royal yacht "Victoria and Albert," at the time Queen Victoria crossed over to Denmark for the Prince Consort.

W. R. Sexton Boiler Setting Co., 127 D'Arcy St., Toronto, location, Machinery hall, represented by W. R. Sexton in a display of "Nonpareil" shaking and dumping grates, and accessories.

Peckover's, Limited, foot of Cherry St., Toronto, location, Machinery hall; represented by C. R. Peckover, J. G. Near, G. Jolly, M. C. Rice, and J. Gefferson. Display of Monel metal castings and products, also a line of slip-roof treads and an extensive range of steel and steel products.

E. Pullan Wipers and Waste Paper Co., 6 Maud St., Toronto, location in Machinery hall, represented by W. F. Cribbs, display of cotton waste, washed and sterilized "Kleanser Kloths," wiping rags, wash cheese cloth squares and mop cloths.

Prest-O-Lite Co., of Canada, Limited, Hillcrest Park, Toronto, location, Machinery hall. Display and demonstration of welding torches and general welding apparatus, rods and other materials. Represented by Messrs. Judson, Gimble, Pollock, Northwood and Murray Leich.

A. R. Williams Machinery Co., 64 Front St., W., Toronto, location, Machinery hall, represented by Enoch Cronk, who has been with this company for 25 years and has continuously figured in their exhibition activities; A. K. Hasen, Arthur Haynes, and Clifford Toderingham. Demonstration of universal woodworking machine, and of special hardwood floor scraper and polisher. Display of machine tools and shop specialties.

Westco Pumps, Limited, Queen and Abell Sts., Toronto, location, Machinery hall, represented by J. F. S. Madden, D. B. McWilliams, C. Templeman, J. L. Johnson, Claude B. Owen, and G. L. Gardner, in a display of standard tankless water systems, equipped with dual automatic valves for hard and soft water; a one-horse power greenhouse pump; ten-horse power boiler-feed pump, oil burner pumps adapted to a wide range of pumping requirements.

Wayne Forge Machine Co., 191 Adelaide St., W., Toronto, location, Machinery hall, represented by Mr. Watson, Wilfred Bolton, and Geo. Morley. Display of industrial furnaces and appliances—heat-treating furnaces, candy furnace, , bench forge, soft metal furnace, gas soldering irons, blowpipes, Bunsen burners, gas-fired tailor irons.

Webber Machine Co., 848 Dupont St., Toronto, represented by R. H. Webber, and Roland Smith; location, Machinery hall. This display is a demonstration of the Webber cylinder grinding machine and of the Webber products for the motor car and garage trade—piston rings, gears, flywheel ring gears, axles and drive shafts and wrist pins. It is claimed for the Webber cylinder grinder that it is the only one of its kind built in Canada, and that it has had a satisfactory record in the three years it has been on the market. The machine weighs 2,500 lbs., is of sturdy construction and is meeting a demand from a growing garage and machine shop field, equipped to give efficient motor repair service.

Wyatts Products, 225 Richmond St., W., Toronto, location, Machinery hall, displaying a line of blow-off valves and other steam specialties.

Wallace Barnes Co., Hamilton, location, Industrial building. Display of springs for great variety of purposes—phonograph, motor, clock, flat steel springs of all kinds, valve and other compression type, extension and torsion springs, brush holder and special flat coil springs, in tempered steel, brass and phosphor bronze, also spring washers.

P. B. Yates Machine Co., Hamilton, location, Machinery hall, represented by Mr. Avery. Display of machinery as follows: Double end box nailing machine, nailing a box together in three strokes, planer and matcher and a G2 edging and ripping saw.

* * * *

Canadian Ice Machine Co., Ltd., Villiers St., Toronto, location, Machinery hall, represented by C. H. Bower, displaying a one ton refrigerating unit complete on one base, including three horse-power motor. This machine is suitable for butcher shops and grocery stores. The exhibit includes fittings and different apparatus in connection with refrigeration.

Canadian Link-Belt Co., 265 Wellington St., W., location, Machinery hall, represented by E. C. Burton, R. C. Turner, and F. M. Corrant. Display of various sizes of malleable chain, malleable buckets, sprocket wheels and a moving exhibit of a silent chain paradox which demonstrates the action of the joint construction in link-belt silent chain. There are also large photos of Link-Belts installations of conveyors, coal and ash handling equipment and photo of locomotive cranes.

Carter Welding Co., 165 Adelaide St. W., Toronto, represented by H. W. Carter, F. Archer and P. Sorley, location, Machinery hall. Display and demonstration of Rego welding and cutting apaparatus, welding supplies, acetylene generators and fuseon metallic flux for repairing scored cylinders of any kind, including auto cylinders and water jackets. The display also includes the "Little 6" a new low-price welding and cutting outfit for use in garages and machine shops and applicable to a great range of uses particularly in carbon moving, lead burning and radiator repair, or work of that kind in connection with a car, truck or tractor. Though the generator is of medium pressure the efficiency of the outfit is shown by the fact that either high or low pressure torch may be used. The entire display is an example of the development that has taken place in this kind of equipment and in the increasing adaptability of price to meet every circumstance. Cutting and welding demonstrations in this exhibit employ steel, cast iron, aluminum, brass and other metals. Methods employed in using fuseon metallic flux in the treatment of auto cylinders and water jackets is also shown and form an interesting section of a creditable exhibit.

Cleveland Pneumatic Tool Co., 84 Chestnut St., Toronto, location, Machinery hall and Arena annex of Automobile building. Represented by C. D. Garner, A. W. Hughes, Toronto, and R. E. Johnston, Montreal, for Machinery hall display of pneumatic tools and appliances. Featured here will be a new ball bearing emery grinder with ball bearing wrist connections on the crank shaft. There will also be a display of valves, couplings and other accessories. Of interest to the motor trade will be an exhibit of air springs for motor cars. This location is in the arena annex and representatives in charge are F. H. Burr and Mr. Wallace from Cleveland headquarters.

Delaval Co., Peterborough, location, Machinery hall. Display of centrifugal pumping equipment for steam and electric drive.

Diamond State Fibre Company, of Canada, Limited, 235 Carlaw Ave., Toronto, represented by T. E. Webster, T. J. McFadden, R. Ray and H. E. Ballard, location, booth 80A. Industrial building. This is a display of fibre in sheets, rods, tubes and special shapes and is a demonstration as to the extent to which this material is now being employed for industrial purposes, especially in the electrical, mechanical and transportation fields. The material, a high grade of vulcanized fibre, is claimed to be tougher than horn, almost as hard as iron and yet lighter than aluminum. Besides being impervious to oil or grease, it does not crack, split or break with ordinary use. It has a tensile strength of from 12,000 to 15,000 lb. per square inch, has high insulating qualities, is non-corrosive, may be secured in various colors and is employed in the automotive industry for battery box linings, brake bands, bushings, conduits for wiring, gaskets, insulators, speedometer gears, switch handles, washers, and in connection with starting, lighting and ignition systems. It has a wide application in the electrical field for bushings, cleats, commutator rings, lightning arrestors, parts for dynamos, and motors, handles, etc. In the mechanical field is is employed for brake shoes, friction straps, pinions, pulleys, pump valves, built up gears and many other purposes. In the

Enters Second Half Century in Machinery Business

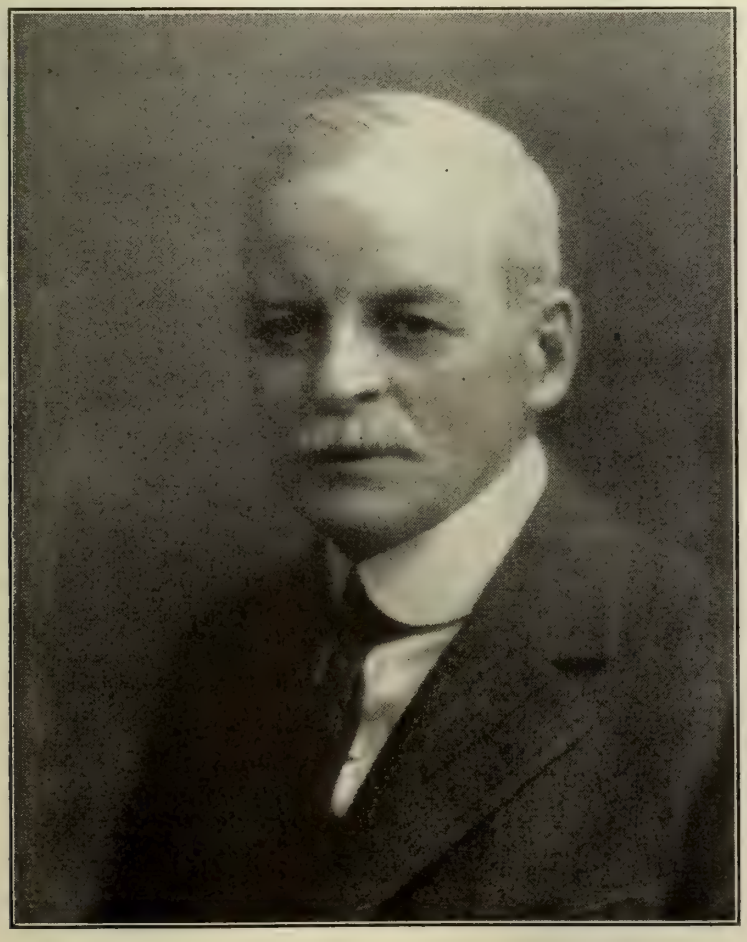
H. W. Petrie Has Carried on Since 1871—Moved from Brantford to Toronto 1890—Since 1876 Warehouse Sales Account for 37,000 Machines—Early Advertising Lists Reveal Interesting Prices—Fifty-Year Record Shows Seven-Year Cycles—Country Always Comes Back

WITH the present year, H. W. Petrie, of H. W. Petrie, Limited, Toronto, enters upon his second half century in the machine tool business. Continuously, since 1871, he has carried on. To-day the name may be said to be synonymous with machinery, and the place of business, near the Union Station, in the old Cyclorama building, may be almost regarded as one of those landmarks that gives distinctive identity to a locality. Mr. Petrie's business did not have its origin in Toronto, but in Brantford. Even at that time, Brantford was a thriving town, and prominent in its industrial roster were such names as Waterous, Cockshutt, Massey and Paterson. It was in 1890 that Mr. Petrie, seeing greater opportunity in Toronto, moved thither and leased from the city that piece of property extending west from his present building to Simcoe Street, on the south side of Front Street, and this took in the site on which the present Union Station is built. It gave him a central display station for his array of boilers and other equipment, and some of the property is used for that purpose to-day.

That New Station

It may be regarded as a notable fact, that Mr. Petrie has passed through the remarkable experience of seeing a new Union Station projected, completed and actually in use in Toronto, for the present building occupies a part of the property which he originally leased from the city. He has a photo of the foundation of the old structure, and he declares that it is his hope to live to see the day when the new building, further east, will be in actual operation. At the present rate of going he may with a great many others, think there is room for reasonable doubt.

Since 1876, there have passed through the Petrie warehouse, as actual sales, 37,000 machines of all kinds. This of course does not take in the number, which if anything would be larger, that has been delivered direct by manufacturers whom the firm represents and which would include the brisk demand of the war period. Since 1876 there have been many changes, and great developments in machinery construction in the matter of gearing, in the range of adaptability, in high speed production and in specialization, but that does not detract from the fact that the old timers were just as wonderful and just as efficient for the purposes of industry in those days as are the modern tools for present day requirements.



H. W. PETRIE
Head of H. W. Petrie, Ltd., Toronto, who this year enters upon his second half century in the machinery business.

Interesting Price Lists

In the matter of machine tool advertising, Mr. Petrie has preserved some interesting records, chief among which is a file of all lists issued between 1876 and 1899. The first of these consists of twenty-six items of used machinery, the first of which is descriptive of a soda water apparatus with marble fountain and attachments complete, offered for $240, the original cost having been $550. There is an upright drilling machine, hand or power, at $28, while an iron planer of Baldwin make, 40x7x7½, was offered for $125. This would hardly buy the metal in such a machine to-day and one of that size would bring down at least $1,000. Then there was listed "one large grocer's coffee mill" at $18, a heavy iron tackle and pair of wrought iron cranks, suitable for windlass, used but little, for $7, while a lot of sewing machine parts, needle bars, feeds, gears, crankshafts, were offered in whole or in part for what they would bring. On the removal of the firm to Toronto, the lists took the form of a catalog, running over 100 pages, each item described in small type detail, and Mr. Petrie declares that the bulk of this work was done by himself at home after hours. A few items will serve to indicate the trend of prices in those days. A new screw cutting engine lathe, 18′ x 12″ x 16″, John Bertram & Sons, was priced at $310; engine lathe, E. E. Abbott, Gananoque, priced at $300; engine lathe, all iron and steel, 7 ft. bed and 17 in. swing, American build, $130; engine lathe, London Machine Tool Co., 6 ft. bed, 14 in. swing, $135. What is now the Canada Machinery Corporation was in Mr. Petrie's earlier days, Cant, Gourley & Co., and later the McGregor, Gourley Co. The succeeding lists of new and used machinery were indicative of business

Montreal Firm Builds Largest Hydraulic Valve in the World

THE rapid strides made in the last ten years in the sizes of water turbine units have naturally called for similar developments in the line of accessory equipment. During the present summer there was installed at Shawinigan Falls, P.Q., a 41,500 h.p. unit, which turbine operates under a head of 145 feet, making 138.5 r.p.m. The last link in the equipment which feeds the water to this turbine is a steel penstock 20 feet in diameter. At the end of this penstock nearest the turbine, is located a Larner-Johnson valve, which is used to shut the water off the turbine, and this valve is the largest of its kind in the world. The valve was designed by the Larner-Johnson Valve and Engineering Co. of Philadelphia, and was built by the Dominion Engineering Works Ltd., of Lachine, P. Q.

Fig. 1 shows the valve assembled in the shop previous to same being shipped. The tapered part of the valve casing, shown to the left in Fig. 1, is made of cast steel, and is composed of four pieces. This section contains the removable seat on which the plunger closes, when it is wished to turn off the water. The first machine operations on this section of the valve casing are to face, drill, spot, and ream the flanges which permit the four pieces to be bolted together to form a circular piece. Fig. 2 shows this work in progress. A large duplex horizontal facing, drilling and boring machine is used. No templates were made for this work. Two of the four pieces were marked off and drilled. Then the four parts were assembled, so that a drilled section was between each section not drilled. Then the locations of the holes in the undrilled sections were obtained by marking same with a scratch awl, using the drilled sections as templates.

As soon as the sections were bolted together work was continued on a large boring mill. The end flanges were faced and the casting bored for the plunger, brass bush, and seat. Some of the principal general dimensions of the valve are: outside diameter of the casing, 23 feet; extreme length, 27 feet; inside diameter of the casing 22½ feet tapering to 13 feet at the outlet. This latter dimension is approximately that of the intake diameter of the turbine scroll casing. The diameter of the cylindrical plunger inside the shell is 16 feet. This plunger has conical ends and can be seen protruding from the casing in Fig. 1. The total weight of the valve is 150 tons and the plunger or moving part weighs 25 tons.

This valve is the largest in the world and is operated by varying the pressure in an annular space, which is located between the casing and the plunger.

That cylindrical section of the valve shown to the right in Fig. 1 is made from heavy steel plate, and rivetted to the cast steel section of the casing. This plate section is rivetted to the 20 foot diameter steel flume. Large brass sleeves line the annular chamber and guide the integral steel rings, (one on the casing, one on the plunger), that seal the ends of the annular space. Thus when the plunger moves, a contact of brass and steel is made.

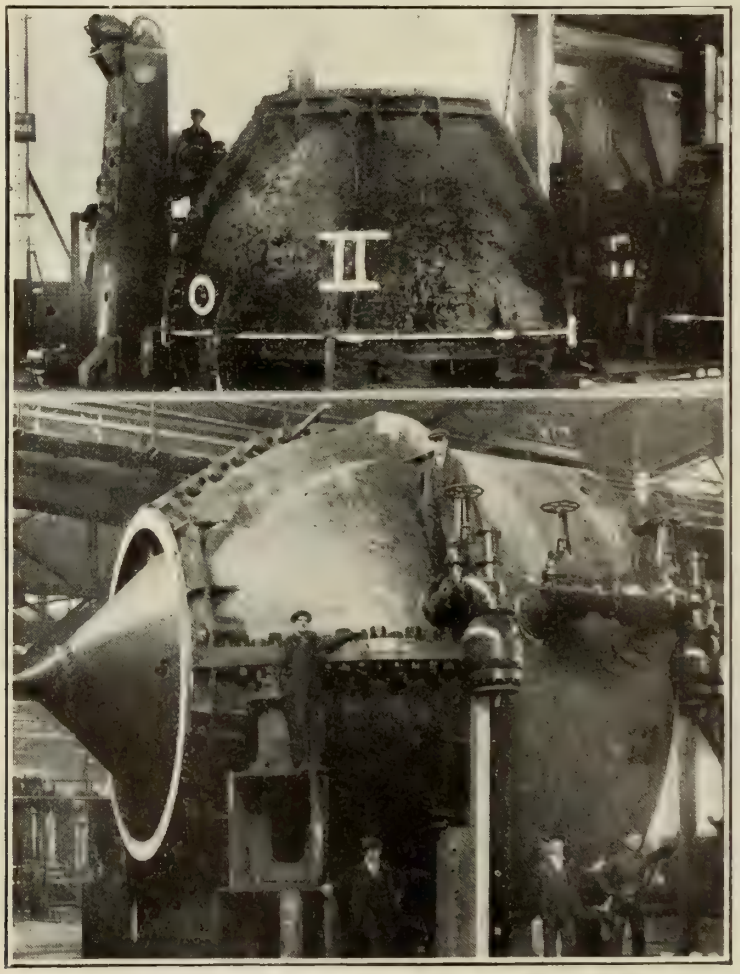

Fig. 1.—Lower: Largest hydraulic valve in the world.
Fig. 2.—Top: Machining the valve castings.

EXHIBITION DISPLAY

(Continued from page 26)

transportation field fibre appears in engine box liners, fishplates, braddock plates, head pieces, switch shims, etc., while bobbin heads, lacing combs, shuttles, spool heads, gears and thrust washers indicate some of its uses in textile machinery production.

A feature of this display is that devoted to radio parts in which another material "Condensite Celeron," a fibre which has the added quality of being waterproof, is used. This product is vulcanized fibre impregnated with condensite and hardened by heating, producing high dielectric and mechanical strength. It is used extensively in the electrical field and is particularly adaptable to radio work. Parts made from it may be punched, shaved, sheared, turned, sawed, drilled, milled, threaded or engraved and in the uncured state may be formed in special shapes. Gears made from the material will stand high speed and, it is further claimed, eliminate noise and vibration. It will take a high polish and is being employed in an increasing variety of uses.

Dodge Mfg. Co., Pelham St., Toronto, location, Machinery hall, represented by W. B. Burrows. Display of Standard Dodge transmission products as well as a complete line of samples of standard products for the transmission of power as well as conveying and elevating.

Dominion Engineering Agency, Limited, 24 Adelaide St., E., Toronto, location, Machinery hall, represented by D. M. Fraser. Exhibit of I. T. E. circuit breakers. Sunah automatic electrical control, high tension equipment, lightning arresters, etc., and other electrical apparatus.

Forged brass pump valve seats are meeting with great favor because of their density and consequently longer life. They can be made lighter and stronger and have a larger waterway, eliminating friction, thereby making a pump using forged brass valve seats more efficient.

Practical Ideas From Practical Men

BELT DRIVE ECONOMIES

By N. G. Near

Very often, when installing a new driving pulley on a lineshaft in the machine shop the problem of proportioning the driving elements, not only for first cost of installation, but for economical upkeep arises. Generally the diameter of the pulley is assumed and the width of the belt is determined by a formulae or rule of thumb. This often results in a heavy, wide, expensive belt. Since the revolutions per minute of the shaft are generally fixed, they cannot be char without altering practically the entire arrangement in the machine shop. By increasing the diameter of the pulleys, a greater lineal speed of the belt is attained. This also increases its driving power per inch of width and so will allow a narrower, less costly belt.

The writer knows a company that wanted to transmit 20 horsepower from a shaft running at two hundred revolutions per minute to another shaft thirty feet away which was to be run at the same speed. The man who had had considerable experience with belts, and who should have known better, used his "judgment," which told him that two-foot pulleys would be sufficient for the job, and on those pulleys he would use a ten-inch double ply leather belt. He struck the belt width fairly close because a good rule to follow for selecting double-ply leather belts is to allow each inch in width, running at 500 ft. per minute, to transmit one horsepower.

The peripheral speed of a two-foot pulley running at 200 revolutions per minute is 1,255 feet per minute. Each inch in width will, therefore, transmit 2.5 horsepower and a ten-inch belt would easily transmit five horsepower. This man's judgment was, in this case, on the side of safety, but his judgment was not on the side of dollars and cents of economy. "How much will it cost?" he was asked by his superior. "Two hundred and forty-five dollars," was his answer. A little figuring on the part of the man higher up who happened to be better versed in belt matters showed that by using a fifty-two-inch pulley, and a seven-inch belt, the cost would be only one hundred and sixty dollars. The eighty-five dollar difference decided the question in favor of the larger pulleys, to be sure. Of course, there is not always room for as large pulleys as extreme economical considerations would dictate but often larger pulleys may be used to advantage.

MAKING COMPOSITION ROLLER MOULDS

By Geo. Barrett

The accompanying sketch and text describes the tooling used in making steel moulds for casting composition rolls used on printing machinery. These moulds are of different sizes but the one here shown is 6 ft. x 3½ in.; bore and outside must be within .004 in. in dia., and a fine smooth finished surface. The general layout is shown at Fig. 1. The work is performed on a 24 in. by 18 ft. LeBlond lathe, fitted with a special steady rest A and boring bar holder B. The rest A is of the hinge type, having an adjustable bearing B, Fig. 2, which is raised or lowered by the sliding block attached to the screw C. The rest is clamped to lathe bed and bored in place so as to maintain proper alignment.

The bar holder B, Fig. 1, is attached to the carriage after removing cross slide. This fixture is also bored while in position, and it is split on one side for clamping the bar. The boring bar A, Fig. 3, is of considerable length and must be supported at the extreme end by a hardened steel bush inserted in the hollow spindle of the lathe head. The cutters are made on a special jig and are split in the centre, after being drilled and countersunk, for the purpose of adjusting by means of the screw A. After cutters are inserted in their proper location in the boring bar, they are held rigidly in position by the wedge B. The lubricant is hard oil and is applied to the cutters through a pipe inserted in the bar, the oil being supplied by a rotary pump attached to the lathe. The bar is also cut away at the cutting edges to provide for chip clearance; a necessary detail in getting good results on work of this character.

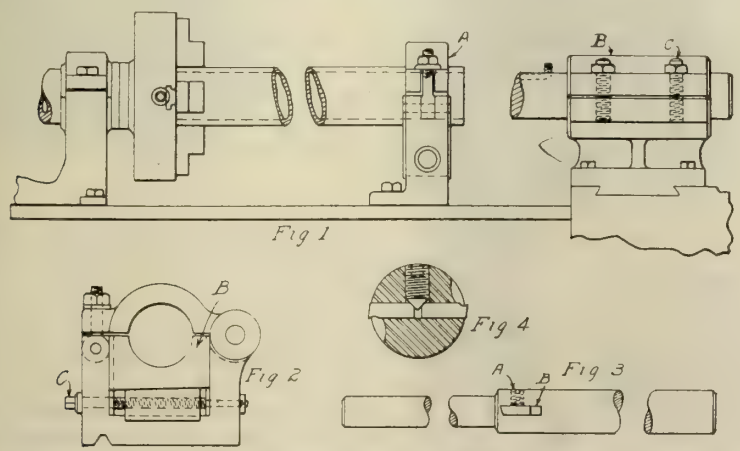

Fig. 1.—General arrangement for boring. Fig. 2.—Adjustable steady rest. Fig. 3.—Boring bar. Fig. 4.—Adjustment of cutters.

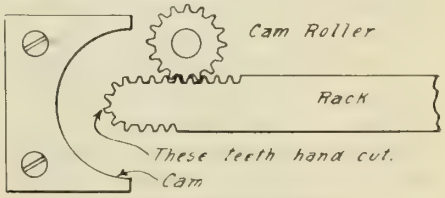
HOW DO THEY GET AWAY WITH IT?

By D. A. Hampson

One of the joys of being a machinist is the joy of service. It used to be that regularly every spring the old maid upstairs would ask you to put up the screen door for her or Mr. Murphy would come over to get you to look at his meat grinder or the people in the next block would want your opinion on



Why the teeth were broken.

how to repair the lawn mower—always thanking you very kindly. But with the coming of automobiles the field has widened immeasurably and we now get requests for every kind of service from judging second-hand flivvers to repairing carburetors—we even get invitations to go riding, couched so beautifully as to disguise the real reason which was to adjust the roadability of some unit of the car.

But not all requests are for auto service, even in these days, as may be noted from one I am going to describe which was complied with for sweet charity's sake. This time it was for service on the washing machine in the Old Folks' Home. "I thought you would like to see this machine," I was told. And before I got through I was very glad that I had had the opportunity—it was a marvelous piece of machinery, and put out by a well-rated American concern too.

Though the Home had had the machine nearly a year, they had been able to turn out only four washes, for every time they started it up a gear broke. The drive was the familiar mangle motion and "the gear" was the bevel pin-

ion that drove the rack back and forth. The matron handed me the new gear—the third replacement—and she also dug out the directions that accompanied them. These follow:

"You are to file the camm on reverse gear yourself as we are unable to do that without frame as they all veary. In filling camm be careful that you do not brake teet in gear, you may have to file gear a littel to fit camm. Cut off pin to suite roller and rivet roller must turn freeley."

Far be it from me to laugh at one's lack of education, but this was a joke indeed, coming from such a concern. Now the startling part of the whole business is not the ignorance of the poor workman who wrote on the tag intending to help the installer but the lack of engineering skill displayed in botching an otherwise good machine. All the discarded pieces had been broken in the same way—reference to the drawing will show why and how.

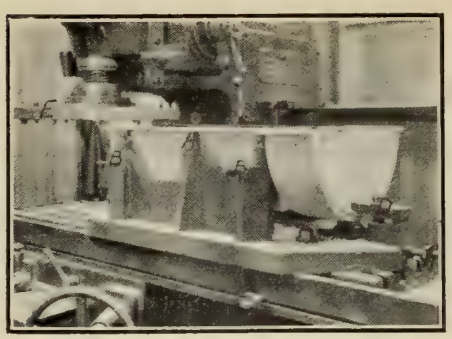
At the end of the stroke a cam encounters the roller on the pinion shaft, causing the latter to work itself around the rack and move the latter in the opposite direction—this is usual on mangles and printing presses which use this movement. However, on this washing machine, the teeth on the ends of the rack were genuine hand cut. That is why the pinions broke and that is why the bench hand in the factory laid so much stress on the shape of the cam. The pinions were cut by the planing process and the rack was nicely milled except on the ends where the workman apparently sawed and filed by eye, sometimes coming out even but more often having to decide for himself that momentous question, "shall I put one tooth or two in the space that is left?"

In this case, it was possible to file down the teeth on the rack ends, selecting the proper side, and by having slack between them and the pinion to produce a job that worked fairly well. The cam was left alone, circular, as it should have been.

MILLING THE JOINT SURFACE ON AN AUTOMOBILE OIL PAN

By Robert Mawson

The Weidely Motors Co., Indianapolis, Ind., manufacture a variety of motors used in some of the high grade automobiles built in the country. The illustration shows the tools and method used when machining the joint surface on one type of automobile oil pan. The aluminum casting is placed on three fixed pins one at A and two one the rear face which are near the outer edge of the piece. Five plunger pins as B, two on the front side as shown, one on the rear and one on each end are then brought against the casting. Those on the sides are operated with the pin headed screw, which may be seen from the illustration. The end plungers are controlled with knob screws, the screw is first slackened, a spring then forces the plunger against the casting and the screw being tightened owing to a wedge surface on the side of the plunger it cannot be pushed back with the casting and thus assists in holding it firmly against the machining stresses. A clamp at each end as D is then fastened onto the piece which holds it securely during the milling work. The fixture is located on the machine table with tongues and held down by means of bolts in the usual manner.



Milling automobile oil pan.

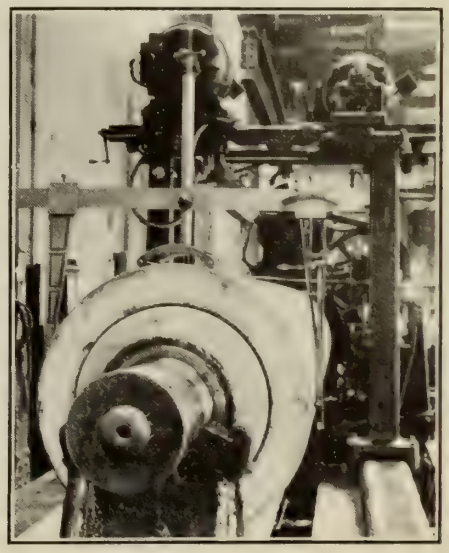
The milling operation is performed with the cutter E. This tool is fitted with cutters made of round tool steel placed into reamed holes and prevented from moving with set screws. These can easily be loosened and the cutters taken out for grinding or when it is necessary to replace them with new ones. The milling cutter is sufficiently large in diameter so that one passing across will machine the entire surface of the oil pan. It will also be noticed that the cutters are placed at a generous distance apart so that the chips will fall away from the face being machined as the surface speed is rather high which has been proved to give the best results when milling or drilling aluminums.

ACCURATE MEASUREMENT OF PAPER MACHINE ROLLS

By H. A. W.

Extreme accuracy in the manufacture of comparatively small machine shop products is very common to-day. The micrometer, the vernier, the indicator, and many other precision measuring instruments are more or less familiar sights to most machinists. All these instruments are, however, designed to be used on small parts with diameters up to six, eight or possibly ten inches.

Now modern paper machine rolls vary in diameter from 12 inches to 48 inches and in most cases diameters have to be exact to a ten thousandth part of an inch. It is also very important in the manufacture of the high grades of paper to have the rolls parallel, that is to say they must be exactly the same diameter throughout their entire length. In the accompanying illustration a granite roll in the shop of the Dominion Engineering Works, Ltd., is shown in the grinding machine with a specially constructed measuring apparatus in position to check the diameter. The bar is set at the proper height so that the contact points on the arms are at the exact height of the centre line of the roll. The arm at the left is moved in till its contact point is touching the roll. The arm at the right is then moved in, till it is also in contact with the roll. It will be noted that an indicator is provided on the right arm. The right arm is always set with the indicator pointer in a vertical position. Then the diameter of the roll is obtained. By moving the device slowly down the roll longitudinally it can easily be seen by watching the indicator if the diameter varies, and if so, in what direction and to what extent. The graduations are such that the pointer will indicate in ten thousandths of an inch.



Measuring paper rolls

In the case of the measurement of calender rolls the crown that is required on the bottom roll can be checked.

BOOK REVIEW

The Radio Experimenter's Hand Book, by M. B. Sleeper, has been prepared for the better instruction of those interested in the development of radio apparatus for experimental purposes. The chief object of this book is to enlighten the novice and advanced student on practical matters pertaining to the construction and operation of radio appliances. One chapter is devoted to the questions on antennae, both for transmitting and receiving; many helpful suggestions are found throughout the entire 16 chapters. A chapter is devoted to radio rules and regulations and includes the latest information on how your antennae should be protected from lightning and meet the requirements of the National Board of Fire Underwriters. This book is published by the Norman W. Henley Publishing Co. Price $1.00.

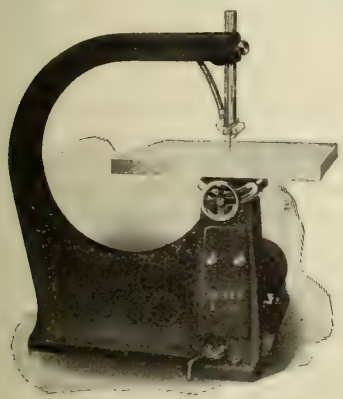
Due to the greatly improved physical qualities and uniformity of form of brass forgings it is often possible to lighten parts appreciably and still retain a higher factor of safety. This feature alone is of great importance in the construction of all apparatus where it is desired to have great uniform strength with minimum weight, such as automotive vehicles, aircraft, etc., and can be compared with the use of special alloy steels for the same reason.

New Things in Shop Equipment

SELF-CONTAINED JIG SAW

A radical departure in the design of jig saw has recently made its appearance on the market. This machine has no overhead belts, no moving parts unguarded and no tension in the saw blade. It is designed for all kinds of interior and exterior scroll work primarily on wood but other substances of course may be sawn on same. It is designed for use in pattern shops and wood-working plants of all kinds. It has a capacity operating from the front of the machine up to 36½in. between the saw and the column but the saw may be operated from the side, that is, the saw turned at 90 deg. so that work of almost any length or practical width may be sawn. The highest work that can be taken under the guide is 10in. The stroke of the saw blade itself is 3in. and saws up to 18in. may be used. All moving parts are very carefully guarded and unlike all other jig saws this saw is operated without tension in the blade so that a broken blade would not be likely to cause an accident. This is the only jig saw, as far as the writer knows, on the market, for which this can be claimed.

The clamping device below the table is automatic and the sliding block in the upper guide way provides a very rapid and convenient method for inserting the saw. There is no over balance load. This feature is unique and insures a steady, quiet running, vibrationless machine resulting in finer and better work. Saws may be turned ¼ way around operating standing against side of machine



Self-contained jig saw.

or at the front of the machine thus increasing, very materially, the length and width of stock that may be worked on this machine.

The jig saw is self contained when belt driven as well as when motor driven. All parts are made interchangeable and all bearings and movable parts are made to compensate for wear. The pitman and the cross heads are made of aluminum light in weight yet very rigid. Complete and easy control of the machine is obtained by means of foot lever located conveniently for operator. The slide dumping device in the table in front of and around the saw, with a knob on the under side, may be drawn back to permit small cuttings to drop through the table and out of the way when doing intricate interior scroll work. A continuous air blast is so arranged that a continuous flow of air is directed to the front of the saw.

The table is of cast iron strongly ri[b]bed, size 39 x 34, mounted on rockers so as to tilt 30 deg. to the right and to the left and it may be locked in any position by means of clamp screw and hand wheel. When direct motor driven, a flexible coupling is mounted on the shaft for direct connection to the motor. The speed of the shaft is 1,200 r. p. m. There are two saw guides, one above and one below the table which may be turned to permit the sawing from either front or side. One dozen assorted blades and necessary wrenches are furnished with the machine. These machines are manufactured by the Oliver Machinery Co., Grand Rapids, Mich.

GEAR DRIVE CRANK SHAPER

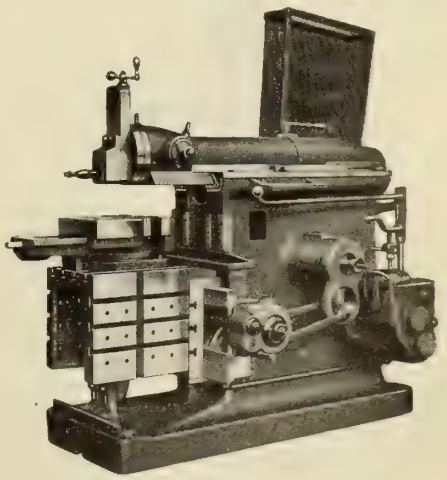
The following is a description of a gear-drive 24 in. crank shaper that has recently been placed on the market:

Advantages which the speed change gear mechanism possesses over the cone pulley drive are its application of greater and more constant power in that the drive pulley runs at constant speed with the speed changes all made through gearing, and the readiness with which this design lends itself to the application of motor drive. No countershaft is required, as the machine can be driven from the main line. The speed change gearing is carried in an oil tight box on the right side of the frame of machine, and it is important to note that the outer projections of this box are well within the dimensions of the floor space required for this machine.

There are but eight gears in the assembly, all alloy steel, properly hardened and heat treated after the manner of motor transmission gears, and are practically noiseless in operation. The gear and main drive shafts are mounted in ball bearings and the gear mechanism runs in an oil bath. Through this gear assembly four speed changes are secured, which with the regular back gears of the machine give eight speeds in geometrical progression. The gear shifts are very easily made with ball handle lever guided by slots in an H plate, and their manipulation is further simplified by the patented quick stop and start clutch controlled by long horizontal lever passing to the front of the machine, which the operator naturally handles with his left hand while making the gear shifts with his right.

The double angle cone driving clutch engages with driving pulley for power and also acts as quick brake when shifted in the opposite direction. This clutch drive is controlled by long horizontal lever at side of frame of machine. It has a very short motion and provides a quick stop and start feature to the ram which is a very important time saver in all classes of work, being of great value in setting of tools, taking measurements, etc. It also simplifies the throwing in of the back gears. Two index plates are fitted to machine, one gives the strokes per minute obtained through the speed change gearing and back gears which run 6-9-14-21-30-46-69-102; whereas the other plate gives the approximate cutting speeds in feet per minute figured for the eight different strokes per minute in combination with the various lengths of stroke of ram from 2 in. to 24 in.

The ram has a bearing of 12¼ in. by 41¼ in., and can be set in any position while machine is running, the length of stroke being shown on index. The crank pin is hardened and ground on all wearing surfaces, likewise the crank pin block. The cross feed mechanism is operated entirely at end of cross rail in all its adjustments. Feed is controlled



24-in. gear-drive crank shaper.

by a dial the graduations on which show the amount of feed. The movement of the table takes place on return stroke of ram. The power down feed operates at all speeds and a graduated dial provides for a range of feeds from .005 in. to .060 in. in steps of .005 in. The machine requires a floor space of 52 in. by 107 in. and has a net weight of 5,680 lbs. It is manufactured by the Hendey Machine Co., Torrington, Conn.

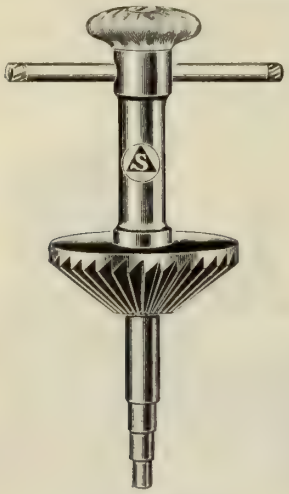
SMALL AIR COMPRESSOR

A single-stage air compressor designed especially for the small shop with light requirements for compressed air, has recently been placed on the market. This is particularly suitable for the operation of small capacity hoists, drills, hammers and similar tools. The machine is of the centre-crank, double-acting type, equipped with belt pulley and fly-wheel on opposite ends of the crank shaft.

All valves are readily accessible due to the overhang of the cylinder, which is fitted with an ample water jacket. High speed, multiple port plate valves are used. Moving parts are entirely enclosed and lubricated by the splash system. The oil is prevented from entering the compression cylinder. The gland stuffing is outside the frame and can easily be reached through the ports. The machine is built in ten sizes, the 6 x 6in. cylinder type having a capacity of 57.6 cu. ft. of free air per min., while the 18 x 12in. machine has a capacity of 748 cu. ft. per min. The compressors may be driven either by overhead belt or by motor on the same level. These compressors are manufactured by the Norwalk Iron Works, South Norwalk, Conn.

VALVE RESEATER AND GEAR PULLER

The two cuts here shown are illustrations of automobile and gas engine repair equipment that have recently been placed on the market. Fig. 1 shows the universal reseater for repairing valve



Valve reseater.

seats on practically all 45 deg. removable head motors. This pilot is one-piece and stepped off for the four popular sizes of valve stems, 3/16, ⅜, 7/16, and ½ inch. Each step is slightly tapered to insure a snug fit in the valve guide. The pilot telescopes into the handle and instantly adjusts itself to any valve seat. The large cutter can fit any job, for it tapers from ⅛ to 3 inches. It is made with extraordinary care from a high-grade tool steel. The design of this tool insures smooth, efficient service.

The cut Fig. 2 shows a duplex gear puller. The body of the tool is a malleable casting, flexible, and strong enough to withstand the severest strain to which a tool of this kind will be subjected. All bearing surfaces are smoothly machined for an **accurate fit** so that they will fully protect the gears being removed. These two tools are made by Stevens and Co., New York.

FORMING TOOL HOLDER

A specially constructed tool holder for use in lathes, shapers, planers and screw machines, has recently been placed on the market. It is claimed that it does the work of forming without chatter, will protect the cutter from breaking and prevents tearing of the work. Two holes are drilled in the cutter, one for the clamping bolt and the other to fit over a dowel for rigidity and assured alignment after grinding. Cutters of any desired forms may be kept on stock and placed in proper position in the holder at any time; no other adjustment is required. The holder is made of tough steel, the bearing surface for the cutter is parallel with the lower side of the shank. Two sizes of holders are made, one to take cutters ¼ x 1 x 1½in., the other for size ⅜ x 1¼ x 2in. These are made by the Willard Tool Co., of Stratford, Conn.

DOUBLE-HEAD LATHE

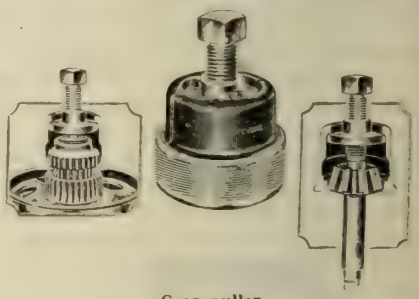
A large double-head lathe, especially designed for the turning of heavy crank shafts and long propeller shafts, has recently been developed. The bed has a total length of 76 feet, but in order to provide a capacity for shorter work, two independent head stocks are provided, one at either end; also two tail stocks and steady rests, this making two lathes in one. A head screw is fittted on either side of the bed, and on long work two sets of cutting tools may be operated simultaneously. The machine has a swing of 72 in. and two shafts 27 ft. in length can be worked on at the same time. Twelve spindle speeds are provided, all being controlled by levers at the operating side of head stock. Hardened steel gears are used on all shifting gears. A friction clutch and brake operated from the carriage or from the headstock is in the drive of each head. Carriage travel is reversed by high speed gearing. Saddle aprons are of double-wall unit construction, all gears being of steel and running in oil. Two 50 h.p. motors are used, both being fitted with automatic starters. These lathes are made by the Betts Machine Co., Rochester, N. Y.

ENGINE-DRIVEN WELDING EQUIPMENT

For the special purpose of generating electricity for welding operations where local power is not available, a self-contained power unit operated by a gasoline engine has recently been developed and placed on the market. The unit consists of a single-operator welding generator geared to a Doman four-cycle, two cylinder, low speed, marine type, gasoline engine. The generator is rated at 175 amp. with a maximum capacity of 225 amp. at 1,750 r.p.m. The unit is especially designed for welding operations so that it is easy for the operator to strike and maintain the arc and likewise to obtain the deep penetration and thorough fusion required for welding. The generator shaft is connected to the exciter by means of a flexible coupling. The cylinder block and removable head is made of semi-steel. The control panel is mounted directly over the generator on an angle iron frame. The outfit is made in both stationary and portable models. They are built by the Westinghouse Electric and Manufacturing Co. of Pittsburgh, Pa.

MULTIPLE-SPINDLE DRILLING MACHINE

Several improvements have been made to the multiple-spindle drilling machine recently developed by the Fox Machine Co. of Jackson, Mich. These changes include the installation of a "Little David" air motor for elevating the drilling head, an interlocking device that prevents engagements of feed gears while air motor is operating. A rotary table has also been fitted to the machine, and the base has been extended to allow for the placing of a motor for individual drive. The drilling head diameter has also been increased from 20 to 25 in. It is possible to index the table for station drilling. The table is elevated by means of a foot treadle while moving to next position



Gear puller.

and is automatically released and lowered to position when proper point is reached. Table revolves on ball-thrust bearings when in a raised position.

BOOK REVIEW

Construction of Radiophone and Telegraph Receivers for Beginners, by M. B. Sleeper, is the title of a new book recently issued by the Norman W. Henley Publishing Co. Those interested in this science can follow the data in this volume in full confidence because each unit of apparatus described has been thoroughly tested and found efficient before the final design was accepted. Regenerative circuits as well as audio and radio frequency amplifiers are described and illustrated by clear photos, diagrams, and working drawings prepared especially for the novice and the man who wants to receive what is being sent out from broadcasting stations. The treatise is prepared in 18 chapters. Price 75 cents.

Consumers and Coal Problems

RECURRING coal problems generally reveal the fact that a surprisingly large number of industries neglect to cover their requirements against emergency, even to a reasonable extent. Expectation that better prices may be available is one of the main reasons for this short sightedness, while on the other hand, not a few plants have inadequate storage facilities. Nevertheless, all this contributes to undesirable conditions at the mines and in the handling and transportation of coal. Trouble in the coal fields is very often the result of an accumulation of problems, many of which work back to the consumer.

Discussing these matters, an authority declares that "coal miners are lying around the mines all summer waiting for jobs. It isn't the fault of the miner but the fault of the consumer who does not order coal until the snow flies. The railroads have their tracks full of empty coal cars all summer, and if they were to have enough coal cars to handle the demand when the heavy consumption is on, they would have to have a lot more cars lying around and a lot more side tracks to hold them. Very few industries have enough room for coal storage. They make contracts for a continuous supply, and that is a mistake. The industries of the country ought to supply more coal storage somehow either on their own grounds where they have ample space, or make it an object for coal dealers to have good size storage yards which could be loaded up beginning with February, by which time the demand is off."

The same authority discussing some of the causes contributing to high prices, points out that the so-called "snow-bird" mines complicate the situation for the regular operators, because under transportation laws they are entitled to get cars according to their shipping ability. These mines only operate when the spot market is very high. They have no contracts, but when panicky buyers go into the market and bid high prices, the "snow-bird" fellow goes to the other mines and takes the labor away from them at bonus rates, until he has all the men he can use. Then, the contract operator, finding his production cut down, bids his men back again at a still higher rate to be able to fill his contracts. There is no reason to think that this same thing will not happen again this winter with all the conditions framing to bring it about.

Thus does so-called human weakness create conditions, but the consumer does not always realize the extent to which he is an important factor in the situation. Canadian buyers, naturally, feel this responsibility, situated as they are at considerable distances from the source of supply, but emergency calls in a market that has "hair-trigger" tendencies certainly do not make for stable conditions.

Wage Rate Differences

SOME SPECULATION was caused among railway shopmen recently when pay cheques failed to arrive on the regular date. It appears that cheques had been made out at the reduced rate of 70 cents an hour, but in the opinion of the Department of Justice such reduction was contrary to law pending reference to a Board of Conciliation. The railways held a contrary view and Premier King urged that the opinion of the Department of Justice should stand in the meantime. The railways have, therefore, rescinded the wage reduction and reverted to rates of pay effective prior to July 16. It is reported, however, that men who for various reasons, have ceased to be employed by the railways since July 16, have been paid off on the 70 cent basis. This is a matter which may also have readjustment.

Enquiry at machinists' headquarters in Toronto shows that skilled craftsmen are fairly well employed with very few idle. Quite a number refuse to consider employment on former jobs under present conditions, claiming they can do better at other employment. There appears to be great variety in wage rates recognized and paid on various contracts and by institutions in Toronto at the present time. One motor car plant interviewed, stated that their rate ranged from 60 to 65 cents an hour; another intimated that they were paying 75 cents for the best men; the Toronto Transportation Commission is paying as high as 81 cents, while at the University of Toronto, on certain experimental work requiring high class men, as high as 87½ cents is the rate. Reports from outside places indicate wages for machinists as low as 45 cents an hour. While employers are of opinion that in larger centers there may have to be further reductions in wages, it is claimed on the other hand that the supply of skilled men is gradually falling below the demand. The assertion is made in well informed quarters that few, if any, competent all-round machinists have been made since 1916, that the great majority of those developed on munitions were specialty men accustomed largely to repetition work, and that industry is approaching the period when it will have to consider the training of new all-round forces. There is no doubt that technical training schools will figure to a certain extent in the solution of this problem, but not before shops will have to take a hand themselves in the development of new crews.

* * * *

So-called authority claims that widows are, as a rule, glad to regain the state of single blessedness. On the other hand, and also to the contrary nothwithstanding, Compensation Board statistics show the average period of widowhood to be about three years. Leave it to the widow.

Demand Active But Supply Has Limitations

Good Market for Structural Steel and Bars—Black and Galvanized Pipe Advances—Premiums Increasing Where Prompt Deliveries Are Required—Continued Strength in Galvanized Sheets—Situation in Montreal

PIG SCARCITY MAY BOOST SCRAP METAL

WITH Canadian producers of pig iron practically out of the market, except so far as their contracts are concerned and with transportation facilities from other sources of supply becoming increasingly difficult, a situation is developing that handicaps the increasing strength of the Canadian markets. Prices in most departments are inclined to advance, and the supply is approaching dangerous levels. Large importers of structural steel and bars to Canadian order, declare that the demand is exceptionally active, not for advance covering, but as a matter of immediate necessity, and that the shipping service is fast approaching the impossible. Even in pipe, both butt and lapweld, which has extensive use in building operations and on which prices have remained at stable figures for some weeks, there is a prospect of an immediate advance. In the American market the price is up two points on black and three points on galvanized, and this means that similar advances will have immediate application here. It does not mean much to the small buyer, but it serves to illustrate the fact that conditions are fast having effect on the entire market. In the pipe market, one point means about $1.90 per net ton.

Reports from Pittsburgh and other stock centres indicate continued decrease in pig iron and steel production. Coal receipts are not adequate to keep up reserve supplies. Meanwhile the strike has not been settled, but some operators are signing up. There is no stampede in this direction, however, and the total capacity that has come into line is far under 50 per cent. of the capacity that was formerly union. Coal storage appears to have affected steel production more than consumption. There is some pressure upon mills for deliveries and when prompt deliveries are required, premiums have increased. So well sold up are they that mills will not have to sell much steel for the remainder of the year.

As a result basis prices have had some sharp advances in bars, shapes, plates and sheets. Quotations, it is evident, have little stability, but the market does not appear to be losing its head and no charges of profiteering have, as yet, made their appearance. It seems to be a case where supply and demand are appreciative of each other's difficulties.

Montreal advices are that it would be difficult to place an order for pig iron with dealers there, unless for Scotch iron. Foundries, however, appear to be pretty well covered, but it would not be surprising to see one or two large shops in the market at an early date. Imported pig is quoted, at dock, $32.50; warehouse, $37.50.

Business on the whole continues to show improvement in Montreal. Sheets continue to be the most active feature of the market. British mills are doing some business there in galvanized sheets. Prices in all departments continue firm.

Toronto

August 23

TORONTO iron and steel markets are active, though reflecting in firm and advancing prices, the increasing difficulty of service. Few extreme cases of shortage in pig iron have developed, however, and if the worst happened it is not unlikely that Montreal sources of supply of Scotch pig iron might be tapped. Prices, however, would necessarily be on a high level basis. Summerlee pig at dock, is quoted at $32.50, and the rate from Montreal to Toronto would be in the neighborhood of $6 the ton. Conditions in the bar and sheet department show increasing problems of supply and prices are unstable and inclined upward.

Scrap metal markets as yet show little activity but continuation of the strike would certainly have the effect of boosting the price of cast iron. This at the present time is exceedingly scarce. Very little buying is being done in any department at the present time, however, and the following prices show practically no change:

Copper, light	per 100 lbs.	8 50
Copper, crucible		11 00
Copper, heavy		11 00
Copper Wire		11 00
No. 1 compositon		9 00
New brass cuttings		6 00
Red brass turnings		6 50
Yellow brass turnings		4 85
Light brass		4 00
Medium brass		5 50
Scrap zinc		3 50
Heavy lead		4 50
Tea lead		3 00
Aluminum		11 00
Boiler plate, per gross ton		9 00
Heavy melting steel		10 00
Axles (wrought iron)		20 00
Rails (scrap)		11 00
Malleable		10 00
No. 1 machine cast iron		20 00
Pipe, wrought		7 00

Prices of iron and steel bars for the present reflect some stability with the demand strong and supply not so easily available, naturally, as dealers would like. Service, however, has been fairly well maintained. The price range is $3.25 to $3.40. Sheets continue in strong demand and the prediction is made in this connection that "galvanized may go anywhere." Current prices:

Iron bars	3 25	3 40
Steel bars	3 25	3 40
Reinforcing bars	3 25	3 40
Steel hoops		4 25
Tire Steel		3 40
Spring steel		7 00
Band steel, No. 10 gauge and 3-16 in base	3 65	3 75
Small shapes		3 40
Sheets, black, No. 28		5 40
Sheets, blue ann., No. 10		4 25
Canada plates, dull, 52 sheets		5 75
Canada plates, all bright		6 00
Galvanized Sheets, No. 28		6 35

Copper and brass products are reported increasingly hard to get and this fact contributes to exceptional firmness. In the non-ferrous metals little activity is reported. Copper prices continue firm, tin has seem some remarkable fluctuations owing to temporary interruption of cable service, but New York reports a return of stability; lead is firm, and in zinc an easing of prices has been reported. There has been a decrease in consumption owing to the strike and to the increased number of retorts in operation. Current prices:

Lake copper	17 25
Electrolytic copper	17 25
Castings, copper	17 00
Tin	36 50
Spelter	7 50
Lead	7 00
Antimony	7 40
Aluminum	22 00

Montreal

August 23

ALTHOUGH the coal strike in the American mining districts has been in progress since April 1st, it is only in the last few weeks that it has had a direct influence on the local iron and steel markets. Business has been improving slowly but steadily for several months. The major portion of the material handled was for legitimate consumption, although in many instances the uncertainty of the situation brought consumers into the market to the extent of covering themselves for some months in advance. Recently when quotations advanced and the mills commenced to exercise caution in accepting new business, buyers interpreted the situation differently. Some have attempted to cover themselves, others feeling that coal and coke would not be obtainable refrained from purchasing. The result is that the local situation is rather complicated. The gross sales have dropped during the month of August to a point slightly below those of July. In past years this has been the usual action of the market, therefore there is nothing unusual in this movement. The United States usually send a considerable tonnage of iron and steel into the local jobbers. Recently this supply has been largely cut off. A few firms who had orders placed in advance are still receiving a few odd shipments. The tonnage, however, is only nominal.

The Canadian mills at the Sault and at Ontario points have ceased to aggressively go after business on the local market as it is felt that their coal supply is not much more than sufficient to care for the present bookings. The local mills are enjoying a very good business with the local jobbers. Orders given the mills by the jobbers have not been large individually, but have been sufficient to keep them busy. The local mills have had no trouble in purchasing billets, and there was a fair tonnage of Nova Scotia coal in this city at the begininng of the summer. Thus, it is felt, that for some time at least, the local mills can take care of local requirements, which have not been excessive for over a year. The mills in the maritime provinces have been able to obtain coal all year, and have been able to handle the more or less limited tonnage that they had booked. Now that the strike has spread to Eastern Canada miners, the situation will, no doubt, become acute, if matters are not settled shortly.

Merchant bars are moving fairly well, and there is a scattered demand for structural steel. Reinforcing bars, steel hoops, band steel, and small shapes still continue to be in demand in small lots.

Sheets continue to be the most active of steel products. Galvanized sheets in varying quantities are arriving constantly from British mills. The demand for this material is such that no stocks are being accumulated. This statement is particularly true of standard sizes and gauges. Black and blue annealed sheets are also moving well.

Small steel products such as nuts, bolts, spikes, nails, wire, etc., are in good demand. Jobbers all are of the opinion that in spite of the uncertainties that surround the market, business is very satisfactory. Matters have arrived at such a point, that if the rail and coal strikes were settled at once, it would be some time before anything like normal conditions would be restored. On the local market the following prices are representative, but at the same time there is considerable firmness:

Iron bars, base	3 15 to 3 25
Steel bars, base	3 15 to 3 25
Reinforcing bars, base	3 15 to 3 25
Steel hoops	4 25
Tire steel	3 25 to 3 40
Spring steel	7 00
Band steel, No. 10 gauge and 3-16" base	3 65 to 3 75
Small shapes, base	3 40
Sheets black, No. 28	4 40
Shets blue ann., No. 10	4 05
Canada Plates dull, 52 sheets	5 50
Canada plates, all bright	7 00
Galvanized sheets, No. 28	7 25

Pig iron. Many of the conditions described above, will apply to the pig iron situation. Prices have undergone a considerable advance in the last few weeks. As far as Canadian iron is concerned, the Algoma Steel Corp., the Steel Co. of Canada, and others, have temporarily withdrawn from the market owing largely to the coal shortage. Nominal quotations on pig run at $36.80 for No. 1. Considerable Scotch iron has been imported, and small lots of Summerlee iron continue to arrive. Summerlee is quoted at $37.50 ex storehouse in lots of five tons and upwards. In lots of thirty tons and upwards a figure of $32.50 on dock is named. One jobber is importing a trial lot of Carron Scotch iron, which it is believed will be quoted at about the same figure as Summerlee iron. For some weeks past a Belgian representative of Belgian, French and German furnaces has been in the city. No large sales have been made in this connection.

Except in the case of Scotch iron, it would be found very difficult to-day to place an order with the local dealers for pig. Most of the foundries in this locality have covered their nominal requirements for some months ahead, and it is not expected that anything in the shape of large tonnages will be booked by local sales offices. There are one or two exceptions to this statement, as at present there are one or two large shops that will be forced to come into the market for iron in the next few weeks. In the list that follows all Canadian iron quotations are nominal, while those on Scotch iron are for actual acceptance.

	5 tons upwards ex Warehouse	Carlots
Algoma, No. 1	$.....	$36 80
Summerlee	37 50	*32 50
Carron	37 50	*32 50

*On Docks Montreal.

Machine tools and shop supplies. Machine tools are decidedly quiet at the present time. Sales have been unusually light for the past year, and at present they have fallen off to practically nothing. Woodworking tools have been moving somewhat better than iron working tools, however. The supply end of the business has fallen off slightly but still is very satisfactory.

Non-ferrous metals. There has been but little activity in the non-ferrous metal market. Tin has stiffened slightly in price during the week. No other price changes have been made. The local demand has remained about the same for several weeks pas . The following are local quotations:

Lake Copper	17 75
Electrolytic Copper	17 50
Castings, Copper	17 25
Tin	35 50
Lead	7 00
Spelter	8 75
Antimony	6 50
Aluminum	22 00

Scrap metals. Very little activity is shown in the scrap metal market. Owing to pig iron being more or less off the market, it appears that interest in scrap has been small and from widely varying quarters The ruling prices locally are as follows:

Copper, light per 100 lbs.	8 50
Copper, crucible	11 00
Copper, heavy	11 00
Copper Wire	11 00
No. 1 composition	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 00
Light brass	4 00
Medium brass	5 50
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine cast iron	20 00
Pipe, wrought	7 00

Pittsburg

August 23.

PRODUCTION of pig iron and steel continues to decrease. Receipts of coal by the iron and steel industry are not increasing, while one stock pile after another plays out. Here and there some good-sized stocks remain.

The so-called "settlement" of the coal strike at a conference in Cleveland, called by President Lewis of the United Mine Workers and attended by many operators of Ohio but few other operators, does not settle the strike. The operators who signed at the Cleveland conference were said to represent 60,000,000 tons annual production out of 400,000,000 tons previously union. This, however, was not 15 per cent. of the total strike, as there are strikes in non-union mines, particularly in the Connellsville region. Possibly the union expected a stampede of operators to sign the scale after the Cleveland meeting, but thus far there has been no stampede. A number of additional operators have signed but as a rule they are small operators, and the total capacity signed up is certainly far under 50 per cent. of the capacity formerly union, while the non-union strikes are continuing.

Guessing at Strike Results

There are various guesses as to what will occur in future. On two points there is a strong preponderating opinion: (1) That the non-union strikes in the Connellsville region will crumble by about September 1, probably with a moderate advance in wages over the scale paid last March, but positively with no semblance of recognition of any union; (2) That the leading operators of the Pittsburgh district, under the leadership of the Pittsburgh Coal Company, will absolutely refuse to sign the national union scale and will hold out as long as necessary for a district settlement with reduced wages and with elmination of the check-off, with an alternative of the district becoming simply open shop or non-union.

Coal production will increase in a moderate way from week to week, but the coal available must be distributed to the more important consumers, and steel consumers will get no preference or priority. Hence there is no definite promise of an early increase in the iron and steel industry's coal supplies and there is merely hope that there will be increased supplies of coal and coke from the Connellsville region. The question then would be whether such increase would offset the further decrease in supplies that is promised by stock piles running out one after another.

It is altogether too soon to predict when the production of pig iron and steel will increase, or even to predict

when the decrease in production will cease.

The best guess seems to be that at the present time steel ingot production is at a rate about half way between 25,000,000 and 30,000,000 tons a year. This would be about 75 per cent. of the recent maximum rate, attained late in June, and about 50 per cent. of the existing capacity.

Consumption Keeps Up

While the production of steel can be estimated with reasonable closeness, the consumption of steel cannot be estimated at all. Shortage of coal affects consumption of steel, of course, but there is no means of guessing how great the influence has been or will be in future. It has been positively reported as long as a fortnight ago that some consumers had instructed steel mills to discontinue shipments because coal supplies had run out, but these cases may not be involving much tonnage.

The appearance in the steel market is that the shortage of coal has affected the production of steel more than its consumption. There is more pressure upon the mills for deliveries than there was a couple of months ago. In the prompt market, in which consumers seek to buy early deliveries, at premium prices, the premiums have been increasing. It would require little tonnage demand, however, to produce premiums, because nearly all mills are already well sold up or oversold. The testimony of the steel market is plain, that steel is scarce, but such testimony has not always proved trustworthy. At the end of a period of heavy demand buyers are always found to have larger stocks than was estimated. This was true even as to 1920, when premiums were enormous, but when the slump developed some large stocks had to be liquidated, one of the causes of the light steel demand being the liquidation of stocks. Everyone was agreed that the consumption of steel in 1921 was considerably greater than the production.

With restricted production and with moderately heavy sales in the past few weeks the mills find themselves much more heavily sold up, in point of time, than was assumed in June. At that time there was a policy among many producers of holding prices down, so as to leave an attractive basis for buyers to take hold for deliveries late in the year. Now it develops that the mills will not need to sell much steel for the remainder of the year. Perhaps it is on this account that basis prices, for delivery as far ahead as mills care to sell, have been advancing rather sharply. Our reports have already recorded advances in bars, shapes and plates to a minimum of 1.80c, for delivery at mill convenience.

All Prices Advancing

The American Sheet and Tin Plate Company (Steel Corporation) has advanced its sheet prices $2 a ton on blue annealed to 2.50c and $4 a ton on black and galvanized to 3.35c and 4.35c respectively. Previously, the company was oversold to October 1 and was not booking any sheet business. Now it does not have its books open to the trade at large but is accepting orders from regular customers, at these new prices. Ostensibly the bookings are for fourth quarter delivery but practically it is likely that much of the tonnage will last over January 1.

All the independent pipe mills, with one or two possible exceptions, have reduced discounts on merchant steel pipe by three points in black and two points in galvanized, a point being about $1.90 a net ton. The independent basing discount is now 68 per cent., while the Steel Corporation continues its old prices, with 71 per cent. basing discount. The Reading Iron Company has issued a new discount card on wrought iron pipe, with a basing discount of 39½ per cent., on 1 to 1½-inch black.

The Pittsburgh Steel Company and some other independent interests have advanced prices to 2.35c for plain wire and $2.60 for nails. Nominally this is an advance of $2 a ton but practically it is $2 a ton on plain wire and $4 a ton on nails, for the advance in nails from $2.40 to $2.50 made by independents early in April held only for a couple of months.

Pig iron is very dull in point of tonnage. Consumers have no thought of buying for late delivery and there is simply a little demand for small lots for spot or prompt shipment. Such demand must be met out of stocks, which are small, there being hardly any current production. Foundry iron is up $2 a ton to $30, valley, and basic is said to be quotable at $26, valley following recent sales at $25.50. Bessemer remains quotable at $27, valley, but it is not certain that it could be bought at this figure.

Connellsville foundry coke is $15 to $16 depending on brand, etc. Both demand and offerings are extremely limited. Prices have shown little change for 30 days.

ENTERS SECOND HALF CENTURY

(Continued from page 27)

expansion and of gradual specialization along certain lines.

Slumps and Comebacks

Discussing slumps, booms, cycles and comebacks, Mr. Petrie states that in 1890 when he came to Toronto, conditions were somewhat discouraging. Vacant houses were numerous and landlords were letting large dwellings free to people who would agree to occupy and keep them in good condition. Banks as usual were advising extreme caution. "In the course of fifty years, one becomes more or less accustomed to recurrences of depression," said Mr. Petrie, "and out of it all comes the confidence that better conditions will always return. That is how I regard the present situation. Our records will show that changes develop about every seven years, and that on the whole, they work out along very much similar lines. First, comes activity in building and then other things follow, always remembering that good crops seem absolutely essential. Business, it seems to me, is much like the human frame. Whether we like it or not, a rest seems necessary to fit it for future progress. I have great confidence in Canada that whatever comes or goes, the underlying assurance is that youth will not be denied and it must go forward."

Mr. Petrie's son, H. W. Petrie, jr., has been closely identified with the business for more than twenty years. Having received early practical training in the machine shop, he subsequently devoted his activities to the sales department. He is secretary and treasurer of H. W. Petrie, Limited.

FIRST CANADIAN GENERAL MANAGER

On Thursday, Aug. 17th, at a meeting of the board of directors of the Grand Trunk Railway System at Montreal, W. D. Robb was appointed ranking vice-president and General Manager. Mr. Robb will thus succeed to the duties of ex-president, Howard G. Kelley.

The board of the Grand Trunk is at present composed of Sir Joseph Flavelle; E. L. Newcombe, K. C., Deputy Minister of the Department of Justice; Graham A. Bell, Deputy Minister of the Department of Railways and Canals; J. N. Dupuis, Montreal, and A. J. Mitchell, vice-president of the Canadian National Railways, Toronto.

W. D. Robb is the first native born Canadian to be called upon to occupy the chief executive office of the Grand Trunk Railway System. He is also the first chief executive of the Grand Trunk to have risen step by step, with unbroken service, from an apprentice with the company. He was born at Longueuil, P. Q., in 1857, his father having come to Canada from Scotland to join the Grand Trunk when it was in its stages of construction. He began his career with the Grand Trunk in 1871 as an apprentice machinist. He was appointed night foreman of the Montreal shops in 1883. In the same year he was promoted to the position of foreman at Belleville in charge of motive power and car departments. In 1897 he was appointed master-mechanic of the mid-division with headquarters at London. In 1901 he was made acting-superintendent of motive power at Montreal. In 1902 he became superintendent of motive power, which position he occupied until in 1917 he was made vice-president of the roa in charge of motive power, car departments, and machinery. In 1918 his jurisdiction was extended to take in th operating, maintenance and construction departments of the system. This position he held until he was created the chief executive.

News From the Industrial Field

Reports from the leather trade indicate an improvement in shoe business with prices quite firm.

Fire damage, estimated at $100,000, was done to the plant of the Graves-Bigwood Lumber Co., at Byng Inlet.

Assured by local dealers that there would be sufficient supplies of soft coal to tide over the situation, Guelph City council has decided not to go into the coal business by purchase of Welsh coal.

Galt union moulders are asking recognition of the 48-hour week. This means a difference of twenty minutes daily in their favor. Employers are not inclined to grant the demand.

St. John, N. B.—The city council recently rejected the Bodell proposal for the sale to the city of the control of the New Brunswick Power Co., with its street railway, power, light, and gas plants.

Montreal.—W. C. Chisholm, general solicitor of the Grand Trunk Railway System, has assumed the duties as head of the legal department, which position was rendered vacant by the death of W. H. Biggar, K. C.

There is some likelihood of the International Nickel Co. making certain changes whereby all of their nickel refining will be done at Port Colburne, Ont. This is now done at Bayonne, N. J.

The Dominion Glass Co. of Montreal has declared a dividend recently and it is stated that plans are being made for the erection of a new plant that will cost approximately one million dollars.

T. H. Watson, president of the Canada Machinery Corporation, Galt, has returned from a trip to the Maritime provinces. He states that there is an outstanding optimism in the East and that industrial prospects are very encouraging.

An all-year freight and limited passenger service between St. John's and the West Indies will be inaugurated in October by the Newfoundland Government, provided steamers can be secured at a reasonable rate. The service will commence with six weeks sailings and if conditions warrant, this will be increased to a sailing every three weeks.

Canadian branches of American concerns continue to be established in various sections of the country. New industries to locate during the past several months are a copper plant in Toronto, cutlery manufacturers at Hamilton and Welland, electric bulbs at Oshawa, automobile plants at Sarnia and Windsor, auto tire plant at Hamilton, and many others.

G. E. Farrel, formerly with Geo. W. Cole, Toronto, has been appointed director of sales for the Canadian Morehead Mfg. Co., Toronto.

Iroquois Falls.—The first of the rolling stock for the Abitibi Railway and Navigation Co. arrived at Iroquois Falls on August 11. The equipment was 12 flat cars for hauling logs. These are the regulation cars 41 feet long fitted with all safety devices.

Brockville.—At a meeting of the Directors of the Canada Foundries and Forgings Ltd., held during the last week, there was presented a report for the first half of the year ending June 30th which showed that the figures for the present year were a marked improvement over those for the same period last year.

Northern Engineering Works' Detroit and Walkerville, have issued a four-page illustrated circular descriptive of their different types of jib cranes. These are adapted for use in shops, foundries and warehouses where traveling cranes cannot very well be employed. There are power and hand operated types and the line comprises the derrick, stiff leg, under-braced, triple braced, top braced and pillar designs. One page is devoted to truck and stacking cranes, both hand and electric.

Ottawa.—The old St. Maurice forges near Three Rivers, Que., are to be preserved as a memorial of the beginning of the Canadian iron industry, and a monument will be erected there by the Canadian National Parks Branch of the Department of the Interior. Founded in 1730, these forges lasted through the French and during the English regime until 1885. There the first Canadian stoves were manufactured, and for four or five generations these forges turned out porridge pots, axes, nails, bars, hammers, spades and shovels. There in 1776, at the time of the American invasion, guns were made for the defence of Canada.

Montreal.—The Dominion Engineering Works have about completed the manufacture of a special machine designed to bore dryer cylinders for paper machines. These cylinders on the larger machines are four feet in diameter and have been built as long as " inches. In order to have them balanced, and to provide uniform distribution of heat, these cast iron cylinders are bored out throughout their length. In the new machine, the cylinder revolves on rollers, while the boring tool has only one motion, namely that of its feed. the cylinders are turned previous to boring, this method of setting up not only saves time, but ensures concentricity.

Montreal.—It is reported locally that the Canadian National Railways have called for tenders on a lot of 1,500,000 ties. These ties are to be manufactured from timber cut between October 1922 and May 1923.

Montreal.—Two of the four floating grain elevators owned by the Harbour Commissioners of this city were placed in commission August 14th in order to accelerate the movement of grain through the port. Grain is being transferred direct from lake vessels to the ocean steamers without the necessity of being handled by the regular port elevators. The floating elevators have each a capacity of 7,000 bushels an hour.

Timmins, Ont.—According to a recent report from Mr. Alexander Gray, the Hollinger mines will take priority over the mine that has hitherto been credited as being the largest gold producer in the world. This mine is the New Modderfontein in South Africa. For the seventh four-weekly period ending mid-July Hollinger reported a profit of $517,895, which is at the rate of $6,732,645 per annum, which figure is more than any other gold mine has ever done.

Ottawa.—On August 15th operations on a small scale were commenced at the plant of the British-American Nickel Corporation at Deschenes, Que. For some time past work has been suspended and it is only lately that conditions have warranted the resumption of activities. Only a small portion of the plant has been put in operation, but S. M. Brown, secretary-treasurer of the company, stated he felt that it would not be long before operations on a larger scale were inaugurated.

Bellville, Ont.—W. S. Springer, of the Springer Lock Mfg. Co., Ltd., stated to a representative of Canadian Machinery that his firm is extremely busy at present. A new wing was added to the factory early in the year, and already, even with this added capacity, rush orders now on the books, have made it necessary to commence working overtime, and it will be three months before the congestion is cleaned up. Other orders, already contracted for, will keep the factory busy until well on into the New Year. All through the depression this factory has enjoyed good business and the firm is optimistic about the future.

Montreal.—The Canadian Car and Foundry Co. have recently started work on 150 street cars for the Toronto Transportation Co. The new cars will be on the Peter Witt type, having front entrance, one man motors, with centre exit, similar in type to those now being

operated on the Yonge Street line in Toronto. Of the order of 150 cars 100 are trailers and the other fifty will be fitted with motors. This work will be taken care of at the Turcott Works. It is also stated that this firm is repairing 500 box cars for the Grand Trunk Railway; a further order for the repair of 500 coal cars is also understood to have been received by the firm. For some time past the plants of the Canadian Car and Foundry Co. have been very quiet and these orders are very reassuring. The officials of the Company state that they have more business in prospect and it is assumed that in the course of a short time further work will be announced.

The steel work for the $20,000 store for the St. Lambert Hardware Co. has been given to the Phoenix Bridge and Iron Works of Montreal.

The steel work in connection with the addition to the high level sub-station of the Toronto Hydro Electric Commission, costing $300,000, has been awarded to the Dominion Bridge Co.

Price Bros. Co. of Kenogami, Que., will construct two pulp mills and 20 residences. They also contemplate the erection of a railway between Kenogami and Saguenayville, Que.

W. E. Dillon & Co. of Toronto have secured the contract for roofing, sheet metal, waterproofing, fire doors and mechanical ventilating system to be erected by dition to the sub-station to be erected by the Toronto Hydro Electric Commission.

The Dominion Bridge Co. has recently closed contracts for steel work in connection with a $25,000 school in Montreal, and the $30,000 field building for McGill University. This firm has also secured the steel and millwork contracts for the extension to Calvin Westminster church at Westmount, Que.; the cost of the improvements will be $18,000. Another contract obtained is that for the steel and cut stone work for the $75,000 restaurant building for the Walton Lunch of Montreal.

Montreal.—It was officially announced from Ottawa on August 16th that the resignation of Howard G. Kelley from the Board of Directors of The Grand Trunk Railway had been accepted. Ceasing to be a director, he automatically ceases to be president of the road. It is understood that the acceptance of Mr. Kelley's resignation at this time arises out of the fact that his contract with the Grand Trunk expires the end of the month. It is expected that h will leave shortly on a long deferred vacation. Pending the reorganization of the Canadian National Board, the Go ernment has appointed Major Graham Bell, C. M. G., deputy Minister of Railways, to fill the vacancy on the Board created by Mr. Kelley's resignation. The question as to the selection of an e cutive head will be dealt with at a meeting of the Board to be held shortly in Montreal.

The Hamilton Bridge Works has obtained the contract for supplying the steel work in connection with the construction of a $100,000 school building at Mount Hamilton, Ont.

The reinforced steel contract for the $190,000 school and residence to be erected by the Montreal Catholic School Commission has been given to the Trussed Concrete Steel Co. of Montreal.

The contract for the steel work and reinforced concrete for a $200,000 church in Montmagny has been awarded to the National Agricultural Machinery Co. of Montmagny, Que., and the Trussed Concrete Steel Co. of Montreal.

Announcement is made of the incorporation of Joyce Bros. at a capitalization of $45,000. The company will carry on a business of structural, civil and mechanical engineers, builders, etc. Offices will be located at Bronte, One.

Montreal.—Business is improving each month with the Dominion Engineering Works Ltd., at Lachine. Among the larger work now going through the shops are two 28,000 h.p. turbines for the Winnipeg development and three of the largest type of paper machines yet built. These latter machines will be installed in one of the local mills on the St. Maurice river. The paper is produced at the rate of one thousand feet a minute in widths of 166 inches. In the month of June the foundry produced 800 tons of castings, while in July over 1,000 tons were poured. In addition to the above work there are many smaller orders.

Montreal.—August 14th more than one hundred members of the Boards of Trade of Cornwall and Alexandria inspected the Port of Montreal as guests of Dr. W. L. McDougald, president of the Harbour commissioners. The party arrived in the city at noon and took lunch at the Windsor hotel before making the trip round the port on the harbour commissioners' steamer Sir Hugh Allan. The same day a large party of members of the American Ceramic Society visited the harbour and made a trip of inspection on the steamer Sir Hugh Allan just previous to the trip taken by the Cornwall and Alexandria representatives.

Montreal.—For some months past the City Council has been considering the assessment valuation of the C. P. R. Angus Shops. On one or two occasions it has been announced through the Press that the matter had been settled. However, it was under discussion on August 14 and the figure of $1,000,000 was finally decided upon as the amount of the assessment of these shops and the figure is to remain stationary for five years. The discussion on the above occasion took the form of a debate as to whether it would be better for the city to have an assessment of $1,500,000 for ten years or to take the $1,000,000 assessment and hold it for five years. The latter, as above stated, was finally decided upon.

Montreal.—The Hon. Ernest Lapointe, Minister of Marine and Fisheries, inspected the Port of Montreal for the first time in his official capacity on Aug. 18. After the inspection he proceeded to Quebec, where he will sail on Aug 22 with the Hon. W. S. Fielding, Minister of Finance, on the Empress of Scotland. The ministers will attend the meetings of the Assembly of the League of Nations, and in addition both ministers will take up departmental matters while they are in England and France. The results of their efforts are expected to bring about better trade relations.

Montreal.—The Honorable Ernest Lapointe sent a telegram on Aug. 16th to Joseph Archambault, M. P. for Chambly-Vercheres, advising him that at a meeting of the cabinet an order-in-council had been passed authorizing the Harbor Commission of Montreal to spend the sum of $50,000 for the work preliminary to the construction of the Montreal-Longueuil bridge. This sum is to be deducted from the $5,000,000 voted at the last session of parliament for the improvement of the harbor. Recently the Harbor Commission asked for authority to expend this amount. The preliminary work of the engineers, such as soundings, borings, plans, estimates of cost, etc., will proceed at once, and a report will be ready for the opening of the next session of parliament.

Kingston. — Canadian Locomotive Works, Kingston, are not to be sold to the Baldwin Locomotive Company, or any other company, but will remain under present control and management, according to a report published here. It is stated that an explanatory letter to this effect is being forwarded to all the shareholders who had given options on their stock in the expectation that a sale of the control of the company might be effected. This letter is very brief, and on behalf of F. G. Wallace, president of the company, in whose name the option had been obtained, merely states that it has been found impossible to put the sale through. As to when the works will open up, that is problematical, but it is believed that there is reasonable expectation and hope that they will be opened this Fall, although on this point local officials have nothing to say.

According to railway reports, 25,000 men have gone west to engage in the harvesting of the wheat crops. The return of these men to eastern Canada begins about Nov. 20 and continues until Christmas. Eighty per cent. will have returned before mid-winter.

It is now possible to weld cast iron to steel by electric resistance welding. The majority of failures of resistance are due to the fact that people not thoroughly familiar with the subject attempt to make them without using the necessary precautions as regards cleanliness and freedom from rust and scale on the parts to be welded.

This Machinery List will Surprise You

The Williams Monthly Machinery List is offering some interesting bargains in re-manufactured machinery. There is a large variety and each machine is backed by the Williams Guarantee to give service to the complete satisfaction of the purchaser. That is the basis of the Williams Service behind every sale of new and used machinery.

Shall we put your name on our mailing list?

WISCONSIN ELECTRIC CO. 2940 Sixteenth St., Racine, Wis.

The Hammer With The Human Stroke

HEADS RIVETS COLD

Heads 'em tight or loose, flush, countersunk, or finishes heads any shape desired, and at the rate of:
A rivet a second, sizes up to 3/16".
A rivet in two seconds, size ¼" to ⅜".
A rivet in three seconds, size 7/16" to ⅝".
And on special order we build machines to handle rivets up to 1½" with proportionate rapidity.
Built in eight sizes.
Besides riveting, the High Speed Riveting Hammer does all kinds of peining, swaging, upsetting, etc.
Send us sample assembly parts with rivets or sketch of your work,

and

Let us shoulder your riveting problems.
Send for the High Speed Hammer Book.

ROCHESTER, N.Y.

BUSY INDUSTRIAL BUILDING

Construction or adaptation of a building in which to house youthful industries is a matter which, from time to time, has had consideration by boards of trade, industrial commissioners and committees in thriving municipalities. Belleville has such a building which has enabled the city to co-operate with concerns wishing temporary accommodation. One of the best examples is that of the Walker Power Building, Walkerville. In 1912, the site on which this building stands was so much unoccupied land. To-day it is the scene of thriving industry, occupying the four floors of the modern structure. All power is supplied by the Walker Power plant, independent of the Hydro or any other source. The building represents a cost of $100,000.

On the first floor is situated the Interchangeable Counterbore and Tool Company; Sand Level Company; Peter Smith Heater Company and the Square D Company.

The second floor houses the Pensar Chemical Company and other sections of the Square D Company.

The Timken Roller Bearing Company, the Barkol Manufacturing Company and the perforated Hone Company are occupants of the third floor.

On the fourth floor are situated the Jewett Radio Company, the Canadian Coil Company and the E. W. Jefferies Company, Ltd.

The four large floors of the Walker Power Building each cover 14,548 square feet of floor space, making a total of 58,172 square feet. Demand for manufacturing space has been such since the first of the year that approximately only 2,000 feet are still available.

ST. CATHARINES GOING 100%

M. M. Maxwell, manager St Catharines Chamber of Commerce, comments as follows upon industrial conditions in that locality:—

"St. Catharines and district is at present time operating at practically 100% production, based on 1912 and '13 production. Some plants are slightly low while others again are running full, so that the average is good.

"During the past few months there has been a steady improvement and managers are very optimistic as to the outlook. Several are buying stocks ahead in anticipation of an increase in production and preparing for a comparatively steady run. In the majority of instances at the present time there appears to be a feeling that the winter months will not see more than the ordinary reduction of activity. At the present time there is practically no more than normal unemployment and compared with one year ago the situation is very much improved so that the coming winter is not viewed with as much concern as was the case a few months ago.

"It would be difficult to specify any particular line of trade which shows definite increase in production or improvement in condition as practically all lines appear to be affected about the same.

"Agricultural conditions in the section are very good and retail business as a result is anticipating a good fall and winter business with the combined activities of agricultural and manufacturing lines showing improvement.

"The outlook for new industries is fair. One new industry has been located within the past few weeks and negotiations are under way with several. There are a good many so called industries looking for locations but the majority of these are in need of financial assistance, which is not looked upon favorably by the people of this district. The city is ready to render such assistance as may be possible to good substantial industries, but many of the projects proposed during recent months have not been of this kind, but appeared to be more the hope of some individual with an idea that someone else will furnish the cash to test out the idea. We believe that Ontario municipalities would be wise to investigate very thoroughly projects before giving them any special encouragement."

PROSPERITY IN VICTORIA, B. C.

Through George I. Warren, industrial commissioner, Canadian Machinery has received the following with reference to industrial conditions in Victoria, B. C.:—

After many years arduous work by those interested, it has been decided to start a rolling mill and smelter in the vicinity of Victoria for the manufacture of iron and steel. This undertaking will have both federal and provincial assistance and the British firm of Vickers, Ltd., is also engaging in the enterprise. Every effort will be made to have the plant on the Island. There are excellent iron prospects here, and the iron mines at Jordan River on the West Coast close to Victoria are very rich.

A movement is afoot at present to amalgamate the adjoining municipalities with the city of Victoria and thus create a Greater Victoria. This idea has much to recommend it, and is being considered by a civic and municipal officials. If it is carried through, Victoria will embrace the Oak Bay District, the Saanich Peninsula, Esquimalt, and Sooke; and will cover an acreage of approximately 200 square miles. A central water board for the districts has already been established. Such an important and far-reaching movement must come about slowly, but when once established it would mean a wonderful future for this city and the south end of the Island.

There has not been so much evidence of prosperity in Victoria since several years before the war. Building statistics are the best proof of the growth of any community, and the number of permits issued this year far exceeds that of many years past. Among the buildings in course of construction are two banks, the Bank of Nova Scotia and the Bank of Toronto. The opening of the Hudson's Bay stores on the upper part of Douglas Street has meant the enlargement of the business district, and the erection of many new offices. One of the largest new stores is that of Woolworth Co. on the corner of Douglas and View streets.

A very hopeful indication of the growth of overseas trade is in the utilization by the Canadian National Railways of the new Outer Docks at Ogden Point, where steamers call now for shipments of cement, roofing, whale oil, etc. The tonnage at this port has been exceptionally heavy this year; several new steamship lines are in operation and there is a large increase in shipping from Oriental ports and via the Panama Canal.

Industries in the city include lumber, shingles, boxes, paper, soap, paint, varnishes, oatmeal, oil refining, ship-building, iron works, ship repair plant foundries, sand and gravel, boiler making, stove making, breweries, mineral waters, cement, explosives, machinists, bricks, marble, sheet metal, dye works, laundries, phonographs, creameries, cooperage, roofing material, carriage work, upholstery, tents and awnings, mattresses, furniture, toys, fish canneries, fruit canneries, flour, rice, coffee and spices, manufacturing confectionery, jam, pickles, boat-building, lime kiln, biscuit, seed-growing, nurseries.

Development within the last two years has secured successful results with home weaving, to the extent that many articles are now being made from Island wool, and rabbit fur, the whole work, to the finished tweed and woollen goods being made on the Island. This is an industry which could be greatly enlarged and would very much interest the tourist trade. Vancouver Island is admirably adapted for sheep-raising and Victoria is the logical centre for a big textile mill. Half a million was invested by the Government on the Island under the instrumentality of the Provincial Industries Act, during the past year. Among the industries assisted were fish, by-products, sawmills, plant for manufacturing electro-plate fixtures, furniture, model-making, fish curing, yacht and boat building, antique furniture.

Although the unemployment problem was very acute all over the continent, and Victoria experienced the difficulties attendant upon abnormal conditions in common with other cities, indications so far, go to prove that times are returning to normal, and that the coming winter will not be a hard one in the above respect.

Vancouver, B. C.—J. G. Kerry, hydro electric engineer of Toronto, has been chosen by a special committee of the City Council for the position of consulting engineer in connection with Vancouver's proposed hydro-electric development. If Mr. Kerry's appointment is confirmed he will be asked to investigate and report on sites that might be available for hydro-electric purposes adjacent to the city.

Canadian Machinery & Mfg. News
143 University Avenue,
TORONTO, CAN.

BRANTFORD BRASS FOUNDRY COMPANY
BRANTFORD, ONTARIO
FOUNDRY AND OFFICE 25 LEONARD ST

June 27th., 1922

The MacLean Publishing Co., Limited.
Toronto, Ont.

Gentlemen;-

We wish to inform you that we have had quite satisfactory results from our advertisement in Canadian Machinery and Manufacturing News, which runs under the classified heading " Where to Buy your Castings ".

Yours Truly,
Brantford Brass Foundry Company.
per David McMaster

If what you need is not advertised, consult our Buyers' Directory and write advertisers, listed under proper heading.

HINTS TO BUYERS

ATKINS Sterling Quality SAWS

When in need of Circular Metal Cutting Saws, Hack Saw Blades, Hack Saw Frames, Kwik-Kut Power and Metal Cutting Band Saw Machines we will be pleased to have your specifications.

"A BETTER SAW FOR EVERY USE"

Address the nearest point below

E. C. ATKINS & CO.

Canadian Factory, Hamilton, Ontario
Branch House, Vancouver.

Built to Give Satisfaction

BLOUNT Grinders are built to stand up under the hard service which is the usual lot of a grinder. They are just as good in every detail as we can make them. They are fast, accurate, strong and rigid—dependable in every sense. Let us send you full particulars.

"We will accept Canadian funds at par."

J. G. Blount Co.,
Everett, Mass. U. S. A.

-A Small Heavy Duty Lathe
-With 32 Thread Changes

THE
ROCKFORD "ECONOMY"

This double back geared, quick change engine lathe brings many advantages to the tool room. High grade, accurate, small in size but extremely powerful.

All gears are cut steel and covered to safe-guard the operator. A lead screw is used only for chasing. Sizes 12", 14", 18" and 22" swing. Write for circular.

ROCKFORD LATHE & DRILL CO., Rockford, Ill.

CURING VALVE TROUBLES

Ordinary gate and globe valves are unsatisfactory for controlling solid or viscous substances because they clog frequently. Shutdowns for cleaning and repair of valves add to the handicap of high initial cost.

These valve troubles are inexpensively and easily overcome by using our New Air-Tight Blast Gate.

Write for descriptive Circular 210-T

NEW AIR-TIGHT BLAST GATE
Light, Strong, Compact, Inexpensive, Quick-Acting
Threaded or Flanged Connections.

W. S. ROCKWELL COMPANY

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

THE NATIONAL ACME CO.

MONTREAL, P.Q.

To Holders of Five Year 5½ per cent Canada's Victory Bonds

Issued in 1917 and Maturing 1st December, 1922

CONVERSION PROPOSALS

THE MINISTER OF FINANCE offers to holders of these bonds who desire to continue their investment in Dominion of Canada securities the privilege of exchanging the maturing bonds for new bonds bearing 5½ per cent. interest, payable half yearly, of either of the following classes:—

(a) **Five year bonds, dated 1st November, 1922, to mature 1st November, 1927.**

(b) **Ten year bonds, dated 1st November, 1922, to mature 1st November, 1932.**

While the maturing bonds will carry interest to 1st December, 1922, the new bonds will commence to earn interest from 1st November, 1922, GIVING A BONUS OF A FULL MONTH'S INTEREST TO THOSE AVAILING THEMSELVES OF THE CONVERSION PRIVILEGE.

This offer is made to holders of the maturing bonds and is not open to other investors. The bonds to be issued under this proposal will be substantially of the same character as those which are maturing, except that the exemption from taxation does not apply to the new issue.

Dated at Ottawa, 8th August, 1922.

Holders of the maturing bonds who wish to avail themselves of this conversion privilege should take their bonds AS EARLY AS POSSIBLE, BUT NOT LATER THAN SEPTEMBER 30th, to a Branch of any Chartered Bank in Canada and receive in exchange an official receipt for the bonds surrendered, containing an undertaking to deliver the corresponding bonds of the new issue.

Holders of maturing fully registered bonds, interest payable by cheque from Ottawa, will receive their December 1 interest cheque as usual. Holders of coupon bonds will detach and retain the last unmatured coupon before surrendering the bond itself for conversion purposes.

The surrendered bonds will be forwarded by banks to the Minister of Finance at Ottawa, where they will be exchanged for bonds of the new issue, in fully registered, or coupon registered or coupon bearer form carrying interest payable 1st May and 1st November of each year of the duration of the loan, the first interest payment accruing and payable 1st May, 1923. Bonds of the new issue will be sent to the banks for delivery immediately after the receipt of the surrendered bonds.

The bonds of the maturing issue which are not converted under this proposal will be paid off in cash on the 1st December, 1922.

W. S. FIELDING,
Minister of Finance.

Make Canada Prosperous by Buying Canadian Products

Why go out of Canada for your Hobs and Cutters when we have the facilities for making any type of Hob or Cutter in our specially equipped plant? Write us when in need of standard or special Hobs or Cutters.

When visiting Toronto Exhibition come and see us. We are only a very short distance from the main entrance and will be pleased to show you why our Hobs and Cutters are superior and dependable.

CANADA ILLINOIS TOOLS LIMITED

Designers and Manufacturers of

CUTTERS—HOBS—REAMERS

163-187 Dufferin Street, TORONTO

"I'm looking for Results"

That's the answer one foreman gave us when we asked him about the tools his men used. "What I want to see is the work done—and done right. If a man can turn out a job the way it's called for with a claw hammer and a cross cut saw—let him go to it. More power to him.

"BUT—and I'm making it strong—I've noticed that the men who have been with us longest have the tools that will do the work best. Good tools don't make good machinists, but you'll find good machinists use only good tools. And it shows in their work. When I see a man with a kit of Starrett Tools I say to myself, 'there's a man who knows good tools'. And I can usually figure on him turning out work that's right. So I manage to keep pretty well posted on what a man's got in his tool kit because, as I say,—'I'm looking for results'."

Write for Catalog No. 22 "3" and the Supplement describing the new Starrett Tools.

Old Man Johnson Kicked the Spigot.

Several dollars worth of expensive finishing oil was lost, accidentally of course—but gone forever, utterly wasted.

Old man Johnson is liable to kick the spigot in **your** plant if **you** are still handling valuable oils and varnishes in barrels and drums.

Prevent this danger of loss—install an accident-proof Bowser system. Oils are drawn through Bowser accurate measuring pumps in exact amounts; waste and spillage are eliminated.

Bowser tanks are evaporation proof and the oils cannot "gum up" or deteriorate in quality, no matter how long they are stored.

Booklet C-13 tells how to stop wasteful extravagance.

Bowser Equipment is MADE IN CANADA by

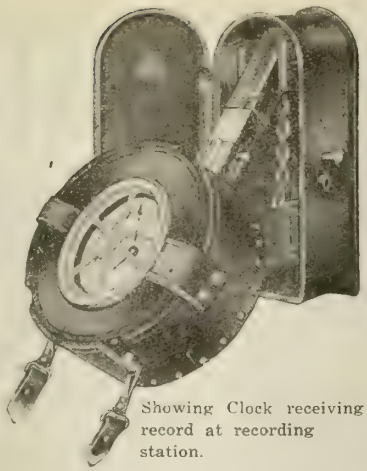
Watch Your Watchman!



Showing Clock receiving record at recording station.

WHEN you pile into your bed every night do you ever stop to realize that you are entrusting, absolutely, the source of your income to a low-salaried watchman **without proof that he is actually "on the job"?** True, you have your fire insurance, but that is merely indemnity for buildings and material destroyed. It pays you nothing for loss of production, organization and time.

The Hardinge Alert System is your Factor of Safety. It tells you, beyond argument, whether you are getting all the protection you pay for. If your watchman is "on the job," it tells you so—if he's a slacker, it tells you so. It cannot lie, the watchman makes the record himself. By his own hand he tells you whether or not he is faithful.

There's no wiring, no complicated installations to the Hardinge Alert; your workman can equip your plant in a couple of hours.

Let us send you a system for thirty days' trial.

Multiple Holding of Gear Blanks on Arbors

Advantages of Gang Cutting Dependent on Accuracy of Holding Fixtures—Work Faces in Contact With Clamping Pieces Must Be Parallel—Truth of Arbor Should Be Tested Frequently

By FRED HORNER

AS IS THE case with the most efforts at increased production, the practice of stringing two or more gear blanks on an arbor leads to extra complications and difficulties in handling. The new problems thus introduced demand careful consideration, otherwise the advantages of multiple cutting become nullified by the presence of inaccuracies in some or all of the gears cut. To a certain extent errors may be cumulative, that is, the more blanks included in the batch, the greater the faults developed. Sometimes this fact arises from errors in the preparation of the blanks, sometimes it is due to putting too many on an arbor that is incapable of sustaining the load or pressure, or which is insufficiently supported as regards bearings, or thrust stays. The particular difficulties encountered in a set of gears often depend upon their shapes, some of the more unusual and complicated designs needing more care in holding, and very likely special blocks or rings or distance-pieces at the ends and intermediate positions.

Stress need not be laid on the obvious necessities in connection with arbor holding, which are alike with single and multiple jobs, namely the provision of true arbors, washers, nuts, and accurately turned and faced blanks. The cumulative errors above mentioned will be induced if any of these items are untrue; thus, if some or all of the blanks have holes not square with the contacting faces, the arbor will inevitably suffer a bending stress, and the teeth when cut will not be anything like a state of accuracy. A careful examination of the arbor (with the indicator), then of the gears loosely dropped over it, and finally of the gears when the clamping nut has been tightened affords the best safeguard against defects of untruth in any or all of the vital necessities just enumerated. Testing the arbor first indicates whether it is bent, or put out of centre; trying the blanks while loose shows if their diameters are concentric with their bores; and the final test after clamping reveals if errors in the blanks have sprung the arbor. Care has to be observed also that the presence of burrs, or grit or dirt between any of the parts in contact does not produce defects of alignment. Multiple holding is always rendered more difficult and exacting because of the fact that rigid support is essential away from the bore (which is not the case with simple lathe arbor chucking) to resist the thrust of the tool or cutter. This means that the flanks of rims must be turned square with the bore of each blank, the troubles increase with diameter, and special means are often necessary for firmness of support at the rim, especially when awkward boss, or clutch, or sleeve extensions occur on wheels.

Design of Clamping Plates

The principal items for clamping a batch of ordinary spur or worm or spiral gear blanks comprise a stout faceplate on the one side and a substantial clamping plate at the other side of the set. To obtain fast cutting times these discs should reach to just below the root of the tooth, taking the pressure and vibration effectually, and the rim stay is located in the most favourable spot for thrust purposes. For all practical purposes the set of blanks

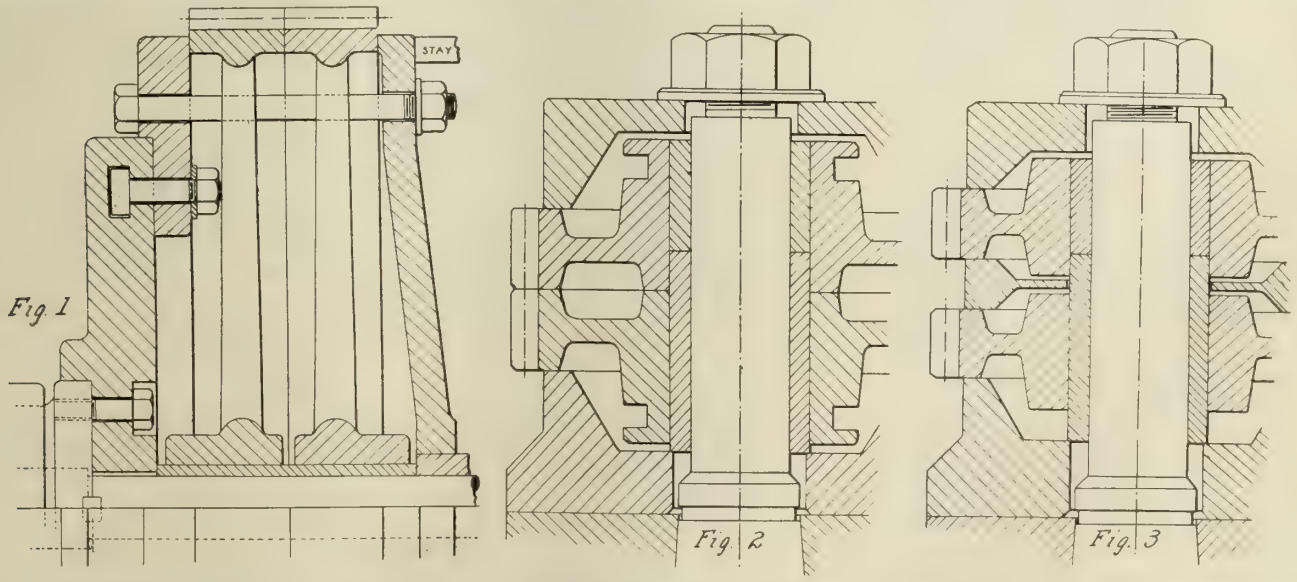

Fig. 1.—Clamping bolts in circle near outside rim. Fig. 2.—Using bushings to chuck gears with square holes. Fig. 3.—Spacer-piece between gears with projecting hubs.

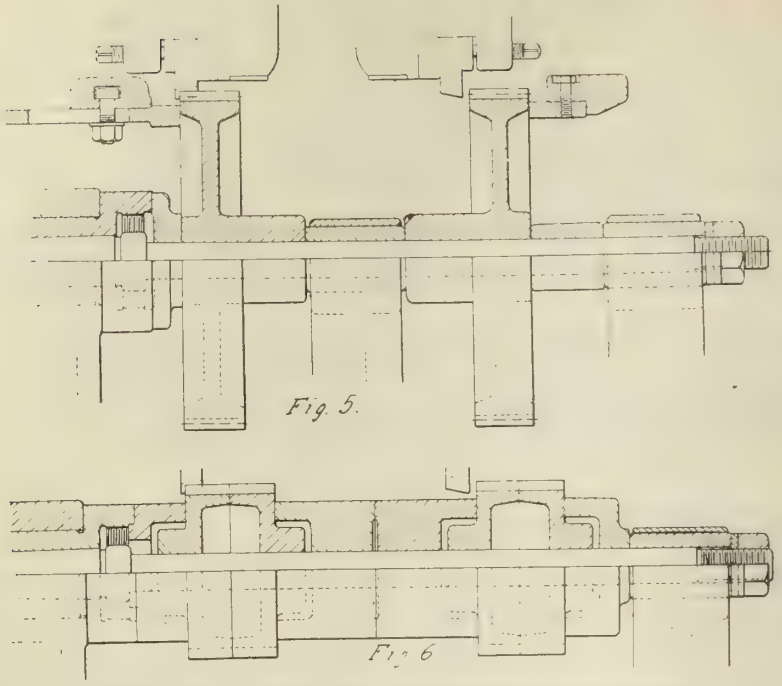

Figs. 5 and 6.—Duplex arbor with intermediate spacing block.

is thus clamped in a vice. Intensive cutting at fast speeds and feeds demands very strong clamping of the faceplate and outer plate, which is best obtained in the larger gears by the use of a set of bolts around the circle, four or six as the case may be; a partial section. Fig. 1, shows this principle. Although the arbor takes care of the concentric accuracy of the blanks, it has little control over the lateral position of the faces, hence primary truth in the faceplate is of the greatest importance. Under those circumstances which happen to call for batches of large wheels for which no suitable clamping plate is available, an alternative plan to make sure of non-slip is to project arms or pegs out from the faceplate, and make these bear on opposite arms of the blanks, so that these cannot twist on the arbor, set-screws or packings being used for the contact and adjustment between one set of arms and the pegs. The hubs are then held merely with a small washer and nut.

Distance Pieces

If the holes in blanks are relatively large, the faceplate may need to be turned with a suitable projecting boss to reach up into the set of bores, as an alternative to the method of interposing bushings to make up the space. Bushings likewise come in usefully to chuck gears by their square holes, such as illustrated in Figs. 2 and 3 (from Fellows' practice). Here one bush is shown extending from the hole in the lower gear to that in the upper, in order to preserve the alignment. The faceplates, it will be noticed, are hollowed out specially to receive the collar hubs of the gears. As the rims and hubs do not come flush on either side in the case of Fig. 3, a special recessed distance-piece is shown interposed to gain a rim packing equal in rigidity to the effect in the previous drawing. Another sort of faceplate modification is outlined in Fig. 4, a kind of drum casting being mounted on the arbor, and turned to receive the ring gears, clamped by a plate and studs.

Various Types of Holders

A recent extension of the principle of multiple holding, as applied to the planing type of machine for generating gears, introduces interesting points in regard to arbor work. The Sunderland generator (made by Messrs. J. Parkinson & Son, of Shipley, England) uses a rack-shaped cutter, and can be set up to cut both on the forward and reverse stroke, using a pair of tool-boxes on the slide, with the clapper actions arranged suitably for tool relief. The blanks and their necessary clamping washers or blocks may occupy the whole working part of the arbor, or may be interrupted by a middle stay-bearing which resists deflection. This is sketched in Fig. 5, which shows the position of the cutters, and the rim stays on the outer flanks of the gears. An instance which does not demand a central bearing appears in Fig. 6 where hollowed-out blocks are utilised to receive the gear hubs. Other designs of blocks show in Fig. 7, with internal setting by the bores in one example, and by the shoulders in the other. From the view, Fig. 8, further variation in holding practice is evident, incorporating not only a special central block, but also bushes to make out the space between arbor, and bore of the gears.

UNIVERSAL DRAWING MACHINE

The engineering draughtsman of today is provided with very much more elaborate appliances than those enjoyed by his predecessor in the 19th century. Drawing boards are now fitted with appliances by which lines at practically any angle may be rapidly drawn on any part of the paper. Earlier types of drawing machines had the objection that there were many projecting parts which occupied a good deal of space; but the latest type introduced by a British firm has nothing at all outside the edge of the board. All the arms are inside and they are so arranged that horizontal lines can be drawn continuously right across the board, and the supplementary scales are propelled along ball-bearing runners so that section lines can be put in very rapidly and accurately. The makers claim that this machine shows a saving of 50% in time in all straight line drawing, as compared with the ordinary loose scales, set squares, and so on.

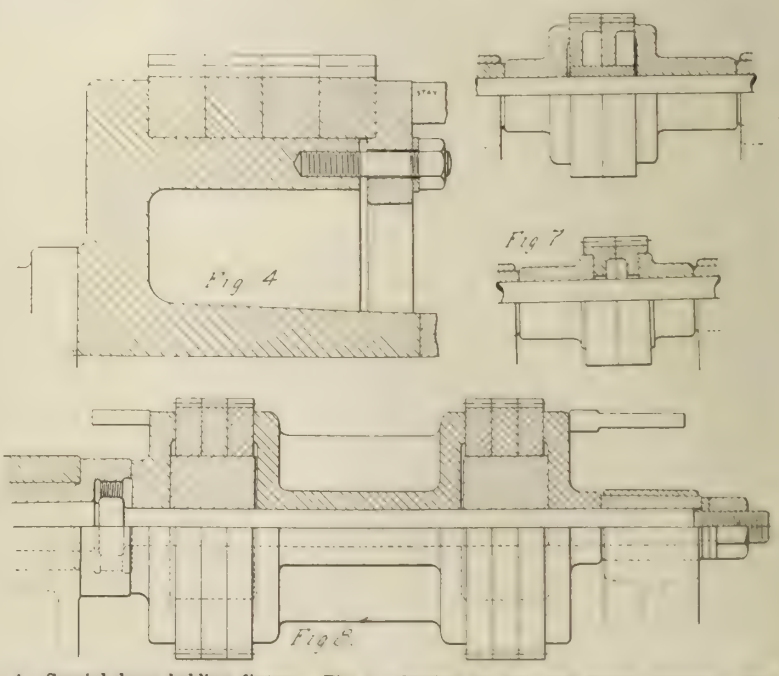

Fig. 4.—Special drum holding fixture. Fig. 7.—Setting by bore and inside shoulder. Fig. 8.—Special fixture for double lots of gears.

Say Conditions Hardly Warrant Wage Reduction

Selling Prices at a Level Which Makes Higher Rates Inadvisable —Some Machinists Taking Other Employment—Differences in Rates Paid—Unwise to Force up Producing Costs—Manufacturers Report Business to be Improving

ACCORDING to opinions expressed by manufacturers, there does not seem to be definite policy proposed on the question of reduction of mechanics' wages. There is a general feeling that wages should come down in view of reductions in selling prices, but with considerable unrest in the industrial atmosphere, and with a decided stiffening in prices of material, any movement in that direction may have to be postponed until more permanent employment is assured and until conditions are fairly free of strike influences. It is a fact that railway shopmen are prepared to fight for maintenance of a seventy-seven cent wage—a higher wage than in other industries—and that they themselves declare that rather than accept the rates paid elsewhere, there are machinists who have taken up other lines of work. This of course, applies to a greater extent in larger centres of industry, but it is a fact that owing to higher wages paid in more active lines, manufacturers in less favored fields find it necessary to come up to those figures in order to hold valuable men. Whether this condition is becoming a permanent problem in connection with labor turnover in a somewhat restricted market, or whether it is merely one of those things that cannot be avoided while industry is anticipating better things, cannot be clearly determined.

An industry with a ready market for its product is in a position to pick and choose, while an industry that is working on a restricted demand will always have the desertion problem on its hands if it cannot afford to pay the shot. This condition must apply where there is not an overplus of help. Where there is such an overplus, wage rates work out to a more or less stable basis.

The prediction is made in authoritative quarters that the time is not far distant, in the return to so-called normalcy, when there will be a decided shortage of skilled labor. In fact, some manufacturers declare that the time has already arrived, while labor organizations who might be supposed to have firsthand information, declare that there is an actual shortage, and that the best indication of the trend of affairs exists in the 20% increase of wages by the United States Steel Corporation. It must be remembered, however, that there are very few firms who can afford to consider a wage increase in its relation to production with as little concern as the Steel Corporation. On the other hand the official explanation is that the advance was necessary because the coal miners had not been compelled to take a wage cut, whereas steel workers had gone back to a pre-war level. It was felt that serious unrest would result in the steel industry unless wages in steel mills were advanced to levels prevailing in other lines of business. Upwards of 200,000 steel workers will be affected by the increase and it will swell the payroll about $50,000,000 annually. Last year with 191,700 employees the payroll was about $333,000,000. The increase brings the common labor rate based on the $3.60 a day to 80 per cent. above the pre-war level of $2 for 10 hours and to 28.9 per cent. below the high rate of $5.06 established in February, 1920. This rate was the highest in the history of the Steel Corp. On May 16, 1921, wages were cut approximately 20 per cent. On July 16, 1921, another reduction of 8.5 per cent. was effected through the abolishment of time and a half for overtime. Finally on August 22, 1921, pay was cut to the 30c an hour rate.

The danger to be guarded against in industry generally, is the too serious anticipation, in the labor market, of the return of prosperity in such shape as to assure a continuance of what are regarded in mining quarters as abnormal prices. Reading between the lines, in many expressions of opinion received by Canadian Machinery, it is evident that manufacturers are for reasonable wages for actual value received. Mutual understanding on that basis will contribute to smooth-running operations.

Thinks Wages Too High

A large engineering firm in Montreal discussing wage tendencies, has this to say:—

"There appears to be a hardening of wage rates at present around current levels, although we know that in the States the United States Steel Corporation has lately increased their wages about 20%.

"Notwithstanding the present hardening of wages, we are inclined to the opinion that the average rate of wages is still higher than what can be considered normal in relation to the cost of living, although if business revives during the next year, it seems problematical to us as to whether wages will be further reduced."

Workmen Prejudice Their Case

A large manufacturer deplores the upward trend in wage rates under present selling conditions. He states, "There has been evidenced in our plant during the last four weeks quite an aggressive movement towards returning to the wage scale in force during the latter part of 1920 and the early months of 1921. In some cases we have yielded to these requests, owing to the fact that we found a number of our men slipping away to Detroit and Walkerville automobile factories.

"We cannot but feel the workmen are prejudicing their own case by forcing costs of production up ahead of any increase in selling prices of products. There have been practically no increases in the quotations of our goods as yet.

"As to conditions of business, we would say that while they are encouraging, there has been also a falling off during the latter part of July and the first two weeks of August. This may be only seasonable dullness. We are still confident that the almost phenomenal crop being reaped in Ontario and Quebec, with an average crop in the rest of Canada, will this fall start the wheels of industry moving more rapidly than they have for a few years past.

"A subsidiary of our company has operated during the past nine months, full time, with a staff of from sixty to seventy-five employees; partly with a view to stocking up in anticipation of heavy demands from certain industries, during the next few weeks, as apparently they are entering upon an era of great prosperity."

Reductions Difficult

A manufacturer in the central manufacturing district of Western Ontario writes as follows:

"We firmly believe that wages will have to come down still further, but still at the same time while the men have only been working short hours it has been a difficult thing to determine to make any further reductions. When full time can be given no doubt the men will be satisfied with a lesser rate per hour and there is no question but that this will have to come.

"Business continues fairly good with us with a tendency to betterment which, of course, will be greatly appreciated when this state of affairs comes to hand.

"Wages here run about as follows:

"Machinists, 50 to 60 cents an hour; moulders, 55 to 65 cents; laborers, 35 to 40 cents."

Don't Demand Overtime Rates

Another manufacturer from the same section as the above, comments as follows:

"We seem to be able to get all the men we need at 45 cents just at the present time, and we don't know that anything will crop up to force us to pay any more in the near future. Our men at

the present time are apparently satisfied to work all the time we want them to, and are not insistent on being paid overtime rates for any odd hour which we might ask them to put in over and above their regular work. Just at the present time we are particularly busy, and have hopes that it will continue, although as things have been going we can look for it to ease up in another month or so.

"Our present rate in our moulding shop is 57c per hour. We pay our fitters and lathe hands from 45c to 57c per hour. We have been taking on some new hands within the last couple of months, and any new mechanics we take on are at the rate of 45c. The highest rates are paid to men we have had all along. Laborers are paid from 35c to 40c."

Conditions Improving

Another Western Ontario manufacturer observes that conditions point to a stiffening in wages. He states:—"At the present time we are paying machinists from 55 to 65c per hour; moulders, 72½c; labourers, 40c. We have found as the demand for mechanics increases that there is a tendency for prices to rise slightly instead of going any lower, so that we question very much whether there will be any further readjustment for some time to come. Regarding conditions in our industry, we are pleased to advise that they have materially improved, and that we are very busy in some departments, and fairly so in others, with fairly good prospects for the future."

A Galt shop writes that they are at present paying machinists, vise and lathe hands, 50 to 60 cents per hour. Moulders, 53 cents to 60 cents per hour. Labourers 35 to 40 cents.

From a large Montreal firm comes the report that they are working 50 hours per week, and employing 480 men. They say they have no trouble in getting men at the following rates:—Machinists, from 50 to 65 cents per hour, according to the skill of the man and the work he is doing. Their average rate is 54 cents. Moulders, from 65 to 75 cents; laborers, from 30 to 33 cents; pattern makers, from 70 to 75 cents; specialists, from 45 to 50 cents; helpers, from 35 to 38 cents.

Wage scales in Hamilton are fairly well illustrated in the following figures from a prominent manufacturing concern in that city, the rate per hour being given:—

Pattern Makers	0 60	0 65
Template Makers	0 50	....
Tool Makers	0 50	0 57½
Die Sinkers	0 52	0 65
Punch Hands	0 50	0 52
Riggers	0 35	0 45
Pipe Fitters	0 40	0 50
Crane Operators	0 43	....
Electricians	0 45	0 55
Locomotive Engineers	0 60	....
Firemen	0 40	....
Carpenters	0 45	0 50
Locomotive Crane Operators	0 60	....
Millwrights	0 45 0 48	0 52

The balance of their employees are all on piece work and their average earnings per hour, according to their ability, are as follows:—

Planer hands	0 40	0 50
Lathe hands	0 45	0 52
Drill hands	0 40	0 45
Blacksmiths	0 41	0 48
Hammermen	0 45	0 50
Shear and punch machine operators	0 42	0 50
Planing mill machine operators	0 40	0 47
Car painters	0 45	0 50
Air brake men	0 42	0 48
Steel and metal workers	0 52	....
Riveters	0 55	0 60
Cabinet Makers	0 42½	0 54
Wood workers on freight cars	0 50	0 57
Freight car truck assemblers	0 45	0 48

It will be noted that a comparison of hour rates paid by the Hamilton concern and the following as paid by a large Montreal plant, does not show very many items of difference.

Plate and angle furnacemen	0 63
Boiler shop flangers and layers out	0 63
Ship platers	0 55
Riveters	0 55
Welders	0 55
Shipwrights	0 55
Loftsmen	0 55
Chippers and caulkers	0 55
Boilermakers	0 55
Anglesmiths	0 55
Machinists	0 55
Plumbers	0 55
Steamfitters	0 55
Blacksmiths	0 55
Pipe Fitters	0 55
Coppersmiths	0 55
Sheet Metal Workers	0 55
Carpenters	0 55
Joiners	0 55
Electricians	0 55
Holders-on	0 50
Burners	0 50
Liner Fitters	0 50
Locomotive Crane Drivers	0 50
Painters	0 50
Drillers	0 50
Ship Riggers	0 47
Scarphing Machine Men	0 45
Motor Attendants	0 43
Overhead Crane Drivers	0 43
Air Compressor Attendants	0 43
Furnace-men	0 43
Planer-men	0 42
Stagers	0 42
Outside Riggers	0 42
Slingers	0 42
Packers	0 42
Firemen	0 42
Light-men	0 42
Jib crane drivers	0 42
Red Leaders	0 42
Heaters	0 40
Reamers	0 40
Rotters-up	0 40
Helpers	0 40

In connection with the above, it is gratifying to note that comments as to general business conditions are very gratifying. Not only does there appear to be a good volume of business moving, but manufacturers seem hopeful of further improvement.

QUENCHING STEEL CASTINGS

An experience of a manufacturer regarding the quenching of steel castings was recently given in the transactions of the American Society for Steel Treating. This quenching was done to improve their physical properties. The castings were mostly shrouded pinions and plain rollers, weighing from 150 to 500 lbs. each. These pieces would be immersed in the water bath for a short time, usually from one to two minutes and then withdrawn and allowed to cool in the air. It was decided to make slight modifications in the treatment so as to improve the results. One suggestion was to provide a tank filled with infusorial earth in which the castings would be placed in order that cooling might be slow and uniform. Another idea was that sodium hydrate be introduced into the bath to make the quenching less severe. It was found that rollers would break in the flange a month or more after treatment. Pinions, after above treatment, were drawn in a furance to 1,200 deg. F. for toughness. If drawn shortly after quenching no trouble was experienced, but this was not always practicable when working on day shift only.

The following statement was made by A. H. Putnam, testing engineer: "It is extremely difficult to make suggestions which will lessen the loss from cracks after quenching steel castings without having more information of this particular case. Some of the factors which are directly or indirectly responsible for these cracks will be outlined briefly below. It is imperative that the approximate chemical composition of each lot of castings be known, as it will be necessary to regulate the quenching and drawing temperatures accordingly. No doubt the loss from cracks will be larger in the casting heats showing a higher carbon content than from heats with a lower carbon content. The method of annealing which is used prior to heat treatment is often responsible for cracks in quenched castings when the original casting structure is not broken down by a sufficient anneal. If ferromanganese or ferrosilicon additions are made in the ladle just prior to pouring castings and the ferroalloys have not completely diffused, this will no doubt cause trouble when the castings are quenched. The length of time the castings are allowed to soak just prior to quenching is very important. The length of time the castings are held at the drawing temperature is more important. The length of time the castings are allowed to remain in the quenching bath will depend largely upon the carbon content and the shape and weight of the casting being quenched. The physical properties which are desired will to a large extent regulate the heat treatment. If the physical properties required are not too severe, often times an air quench or cooling in an air blast from a temperature above the upper critical point and using a low draw will furnish the desired results."

LUBRICATION OF BALL BEARINGS

The function of lubrication in ball bearings is the protection against corrosion and facilitating the longitudinal motion of the journal when such is required. Chemical abstracts states that the lubricant must be free from acids and alkalies (maximum 0.1 per cent.), lime (maximum 0.5 per cent.), resins, and all traces of impurities which might cause friction. The best lubricant is a high-grade oil of suitable viscosity, depending on the nature of the work. If grease is used, it must not melt at the temperature of the bearing. Graphite should never be used for lubricating oil bearings. Simple tests for detecting acidity, alkalinity and resins, and for determining the melting point, should be applied.

Machining Motor Base for the Reading-Standard

Interesting Operations in Machining Motor Cycle Parts—Types of Jigs and Fixtures Used—Milling Cover Joint Surface—Built on Interchangeable System

By ROBERT MAWSON

THE Reading-Standard motor cycle which is made in Reading, Penn, is made by one of the oldest firms in the industry and though they do not make a large quantity of machines, being rather modest as a manufacturing concern, endeavour to make the best, as regards material and workmanship. They are the pioneers in the adoption of the now famous "side-by-side valve" type of motor which was used by them 12 years ago and has since been adopted as the most efficient and flexible motor for motorcycles. This year they are producing only one type the distinct difference being the electrical equipment.

Many of the interesting operations are performed in the machining of the parts for the motorcycle and in this article will be shown and described those followed when making the motor base and cover.

These elements are made of aluminum which is common practice as regards the material used. In Fig. 1 is shown half of one of the finished machined motor bases and will convey some idea of the amount of work necessary to make this part. The first operation on the motor base is machining the parting line surfaces and for this purpose the casting is held in a three jawed chuck on a lathe and the surface is faced. On one part of the motor base is turned a tongue while on the other section is machined a receiving recess to suit the raised portion so that the two parts of the base are located and fit together without depending on dowels as an aligning medium.

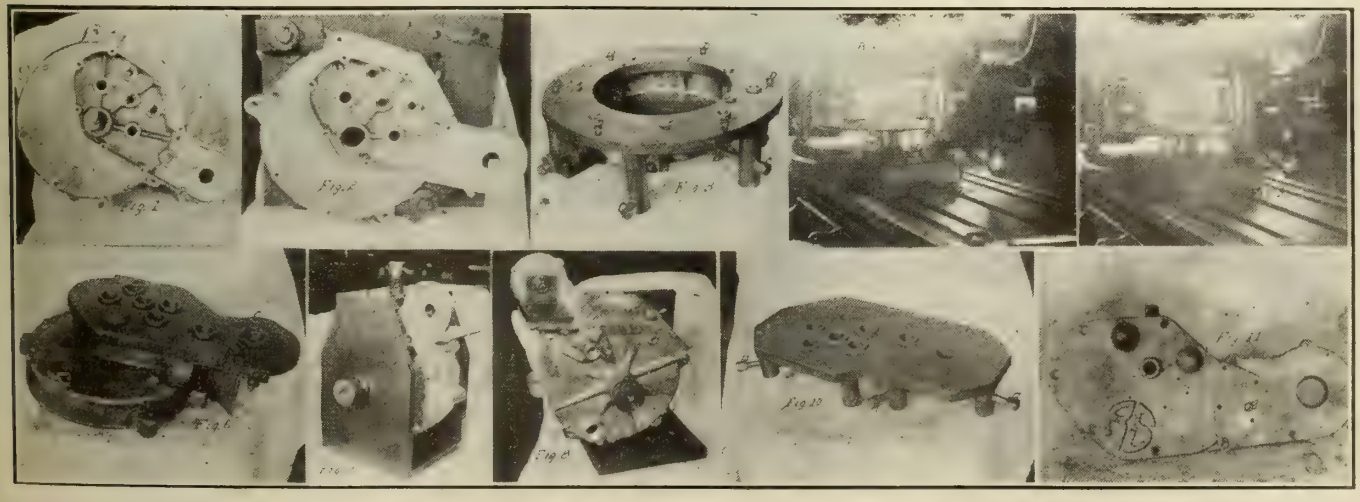
When machining the right hand section of the motor base, or part to which the gear cover is attached, the next operation is machining the joint surface and is performed with the fixture shown in Fig. 2. The casting is placed on the fixture resting on the surface machined in the previous operation and held with the two clamps A. This fixture is of the angle type and the lower side rests on the milling machine table and is located with tongues and held to the table by means of bolts in the usual manner. The cover joint surface is then milled true with the rear parting line surface using a 6½ inch inserted tooth cutter so that one passing of the cutter will machine the entire surface, as the width of the surface is less than the diameter of the cutter.

Drilling For Bolt Holes

The casting is placed into the jig and located by means of the turned register, a mating portion being provided on the tool so that by either attaching this locating tongue or removing it (thus leaving a recess) the jig will suit both portions of the motor base. The casting is then turned around on the locating register and a vee-block operated with the screw A is brought against one of the bolt bosses thus locating the part correctly in relation to the position the holes should be in the bosses. Cams as B operated by the screws C are then tightened against the under side of the casting which force the motor base upward and hold it securely in position. The following holes are then drilled, four 29/64 inch and seven ¼ inch. The jig and casting is then turned over resting with the pins D on the drill press table and the machined holes spot faced by using a standard piloted counter bore. The two parts of the motor base are then fastened together by means of bolts placed in the holes of the parting face and the cylinder's surfaces machined, this operation being performed with the fixture shown in Fig. 4.

The fixture is located with tongues and held to the machine table in the usual manner. The motor base rests on the machined surface A of the fixture and the clamp B is swung around into position. The pin or shaft C is then placed into a hole of the clamp and slid into the large driving shaft holes of the motor base elements, th having been bored and reamed in the first operation when the joint surface was machined. This milling fixture is provided with a base and sub-base, the latter sliding around on a machined center stud. The sub-base is therefore revolved until the locating pin D will enter a bushed hole in the base, the fixture is then in the proper position for machining one of the surfaces for the cylinder, the pad for the magneto is also machined at this time. The locating pin is then pulled out and the sub-base again revolved to the other position. When the fixture is in the correct relative position for milling the other cylinder joint surface, the angle between these two machined surfaces is 22½ deg. on each side of the vertical center line of the motor base or an included angle of 45 degreees. The cutter used to machine these faces is 6½ inch diameter with 12 inserted teeth.

The next operation on the motor base is machining the bores to suit the turned registers on the cylinders, and this work is performed by holding the casting in the same fixture and using it in a manner similar to that prescribed for the previous operation. The only change is to substitute the cutter Fig. 5-A which is 3-⅝ inch diameter also of the inserted tooth type having 6 blades, both holes are bored to this diameter



Jigs and fixtures used in machining motor base of Reading standard engines.

the casting being indexed around as has been already described.

Machining Holes in Right Hand Sections

The jig used when machining holes in the right hand or cover side is illustrated in Fig. 6. The casting is placed onto the pin A which fits in the driving shaft hole, and swung around until it comes in contact with the locating screw B, another screw at the rear performing this function and also holding it in position. The following holes are then machined, 10-13/64 inch for the cover screws, drill and ream 2-⅝ inch holes for the cam gear shafts, drill and ream 2-⅝ inch holes for the cam lift levers, drill and ream one ⅝ inch hole for the compression release cam shaft, one hole ⅝ inch drilled and reamed for the intermediate gear shaft and hole drilled and reamed 1 inch diameter to suit the magneto shaft.

Fig. 7 shows the jig used when machining the valve lift rod guide holes and also the cylinder stud. The two halves of the motor base are fastened together with two or three bolts and placed into the jig being centered by means of the pin A which fits into the driving shaft hole. The motor base is then swung around on pin to its proper relative position which is determined with a plug that fits into the three ⅝ inch hole, this plug being operated with the screw B. When the casting is in the correct location four ⅝ inch holes are drilled and reamed for the valve lift rod guides and eight holes drilled to suit ⅜ inch standard thread studs used to attach the cylinder to the base.

The locating plug is then withdrawn by means of the screw B and the motor base revolved on the large pin to the position for the other cylinder, again being located with the plug fitting in the bored hole of the motor base when similar holes are machined as those already noted. The two plugs are then drawn away from contact in the castings and the machined parts are easily removed from the jig.

Fig. 8 shows the jig used to drill the holes in the magneto pad, the casting is held on the fixture with the stud A which fits into the driving shaft hole. The jig proper is located by a pin B fitting into the one inch magneto shaft hole and a dowel that fits into one of the drilled holes, the face of the tool resting on the milled face of the motor base as shown. When the jig is in position as shown four holes are drilled to suit ⅜ inch 16 threads standard studs, these being used to hold the magneto on to the motor base.

Machining the Motor Base Cover

The illustration Fig. 11 shows one of the finish machined motor base covers with jig for oil pump holes attached and the jig used when machining the holes on the parting line surface is shown in Fig. 10. The casting is located by means of pins that fit against the outside contour of the piece and is held and forced against the face of the tool by means of the screws A that operate cams resting on the under side of the piece, the joint surface having been milled in a previous operation.

The following holes are then machined, ten 17/64 inch drilled, drill and ream five ⅝ inch and one ½ inch hole drilled and reamed. The last operation on the motor base cover is performed with the jig Fig. 11 and is drilling for the oil pump holding studs. The jig is located with a ½ pin at A and a 17/64 inch pin at B both of which fit into holes drilled in the previous operation. When the tool is in position as illustrated four No. 20 holes are drilled. This completes the actual machining operations on the motor base and cover after which they are given a careful inspection and if found satisfactory are ready for assembling into other units to go into the finished motorcycle.

"BIGGEST THING SINCE C.P.R. HIT VANCOUVER"

Press reports from Vancouver, B. C., discuss with considerable enthusiasm the prospect of an iron and steel industry for British Columbia. By prominent business men it is declared to be "the biggest thing that has happened for this province since the C. P. R. built into Vancouver." The Vancouver Sun states:—"An iron and steel industry for British Columbia is assured. Within 18 months a $10,000,000 blast furnace capable of turning out 500 tons of pig iron a day will be employing approximately 5,000 men in the neighborhood of Vancouver. A steel mill will follow within a few years. Industries manufacturing iron and steel products in Vancouver will be enabled to obtain their metal at low cost and Vancouver will be in position to compete in the world market for farm implements, ship plates, and the multifarious products made from iron and steel. Such is the significance, according to local men, of the decision taken by the Provincial Government in pronouncing its determination to put through at the next session of the Legislature a bill guaranteeing one third of the bonds of the Coast Range Steel Company of Vancouver."

The Colonist states:—"Provided that the Dominion Government and the Imperial Trades Facilities Committee will come forward with equal guarantees, the Provincial Government will, through legislation and in other ways, assist in the plan put forward by the Coast Range Steel Company, Limited, to establish the iron and steel manufacturing industry in British Columbia.

"The Provincial Government's promise of aid is further conditioned upon a full investigation into the whole project, covering the company's sources of raw materials, specifications, locations, contracts, management and methods of financing the project, together with the probabilities of success.

"This announcement was made by Premier Oliver following a lengthy conference which members of the cabinet had with H. J. Landahl, promoter of the Coast Range Steel Company, Limited, incorporated under the company laws of the Province with a share capital of $15,000,000.

"Landahl was accompanied by ex-Mayor R. H. Gale, of Vancouver; Mrs. Mary Ellen Smith, M. P. P.; Mr. J. A. Campbell, president of the Vancouver City Liberal Association; and Mr. C. P. Hill, of Vancouver.

"Assurances have been given the Provincial Government that the British Government, through its Imperial Facilities Committee, has agreed to finance one-third of the cost of the project, and that the Dominion Government has signified its willingness to do likewise. With the Provincial Government coming in on like basis, Mr. Landahl has explained to the cabinet, the inauguration of the great project will be assured. He stated that the three largest steel companies in Great Britain are interested in the establishment of the plant in British Columbia, these being Vickers, Limited; Simon Carves, Limited; and Wellman Smith Owen Engineering Corporation. If the necessary guarantees are forthcoming from the Province, Mr. Landahl stated, the Coast Range Steel Company will go ahead with the proposed plan of development and erect blow furnaces, blast furnaces and open electric furnaces, build open hearth steel mills and ultimately produce an outupt of 100 tons of steel per day.

"The share capital of the Coast Range Steel Company, Limited, is divided into 150,000 shares of a par value of $100 each. Following the organization of the company, Mr. Landahl agreed to turn over a number of iron properties, as well as options he possesses upon other similar properties, to the company, receiving therefore 149,992 shares of the company's stock. Other share holders, according to papers filed with the Registrar of Joint Stock Companies, are: Mr. Charles Reid, John D. Kearns, J. Fred. Noble, Zera Strong, Fred T. Congdon, Montague Moore, John Steta and H. J. Landahl, Vancouver, who hold one share each, fully paid up. The directors of the company are: Messrs. Congdon, Kearns, Moore, Steta and Landahl. The properties turned over to the company by Mr. Landahl are located at the following points:

"Fanny Bay, Seymour Inlet, on Wigwam Bay, about fifty miles north of Port Hardy; Klaanch River, near Nimpkish Lake, Vancouver Island; Alberni Canal, Louise Island, Cumshewa Inlet; Burnaby Island, Queen Charlotte Mining Division; Pitt Lake and Harrison Lake; and Mr. Landahl holds options on claims of the International Iron Mines in the Nelson district, Copper River Coal Mines, on Coal Creek, about eighty miles from the G. T. P. station of Van Arsdal; and the North Pacific Mines and the Pocher and Pitt Island Iron Mines."

The hardest working man I know always has good health and plenty of time for pleasure.

Paint as a Means of Greater Production

Poorly Lighted Workshop Now Out-of-Date—Light Well Reflected Enhances Efficiency—Dark Places Cause Accidents—White Painted Walls Improve Morale in the Shop

FACTORY illumination along scientific lines dates back only a few years yet the progress that has been made in the better lighting of industrial factory buildings shows results that are simply phenomenal, both from an efficient and economic standpoint. The passing of the poorly-lighted workshop is only a question of time. Plant officials are rapidly recognizing that the old out-of-date method of lighting —where small individual lamps were strung low down over the benches and machines, with shadows predominating in all parts of the shop—is being superseded by artificial illumination carefully worked out by experienced lighting engineers and factory executives.

Following the practice of the early days of artificial illumination when the candle, the open gas mantle and the kerosene lamp were the common medium of lighting interiors, the first attempts—and likewise those of many succeeding years—of electric lighting continued to be along the lines of direct illumination, where the rays from the source of light were directed on the surface or area requiring the most attention. The inefficiency of this method is now a recognized fact and with few exceptions modern installations are of the indirect system, where the distribution is made more effective by means of scientifically designed reflectors.

Advantages of Reflected Light

The advantages accruing from the adoption of reflected lighting systems and the better diffusion of light resulting therefrom, soon emphasized the importance of having the interior walls and ceilings of factories of such a character as would enhance the general illuminating arrangements. The necessity of good lighting in relation to factory management is quite evident from the following beneficial effects:—better working conditions; increased production; greater accuracy in workmanship; less spoilage; reduced lighting bills; neatness and sanitation of plant; less eye strain; reduction of accidents; improved morale among employees, and reduction in labor turnover.

Aside from the many advantages resulting from the installation of modern scientific electric lighting systems, the proper diffusion of such light is of prime importance. Of all contributing agencies, it is a recognized fact that white paint that reflects and diffuses light is one of the most essential factors in the solution of the lighting problem. In selecting a suitable coating for interior finishing where maximum illumination is of primary consideration, it is imperative that a surface be obtained having good light-reflecting qualities; shows no tendency to chip, flake or peel, and one that may be washed frequently without injury to the finish. In other words a surface that will stay white under all varying atmosphere conditions.

Keep Walls Clean and White

It cannot be denied that clean white walls are an aid to industrial efficiency and an economic necessity. They eliminate the dark corners and minimize the shadows, thus reducing the possibility of accident, and increasing the confidence and good will of the workmen. In coating the walls and ceiling it is good policy to use a paint with a gloss finish white that has a high-reflecting value and insures uniform diffusion of light. Glossy surfaces may be more easily cleaned after becoming soiled, the illuminating value being restored by brushing or washing without injury to the finish. With dark and dingy walls the need of artificial light is often an all-day necessity, but where due consideration has been given to the proper distribution of available light, the utilization of daylight for longer periods, results in a great saving on lighting expenses.

The Influence of First Cost

The initial cost of painting the interior of a factory has often been an influencing factor in determining the character of the coating used. It has been common practice in many large industrial plants to give the walls a coating of whitewash in an effort to improve the general appearance of the shop, but the rapid deterioration of the coating, its susceptibility to absorb dust and dirt, and the inability to clean it properly, has gradually met with disfavor by plant managers and superintendents. With unpainted walls, or those coated with low-grade paint, there is a maximum cost made up of cost of repairs; early repainting; cost of mistakes due to poor light; cost of idleness and accidents; cost of inefficiency; and cost of excess artificial light. It is undoubtedly true that the primary cost of low-grade paint is less than that of the high-class durable quality, but the ultimate cost of the former is often greater when figured over a period of years.

Dark Plants Inefficient

In dark and dingy factories production is invariably below the possible capacity of its equipment and workers. Much of this loss through inefficiency is directly chargeable to poor lighting. It has been stated by illuminating engineers that it takes at least four times as much electrical energy to light a plant with dingy walls as it does the same plant when walls and pillars are painted white. This in itself is an item well worth considering when figuring on initial cost and subsequent maintenance. The higher type of workman is influenced in no small degree by local environment. Shop atmosphere has much to do with human temperament. The clean, well-lighted, sanitary factory has a certain appeal to that class of employee who is a special asset to any organization. Like begets like. If a shop is unclean, dimly lighted and unsanitary, the workers are invariably discontented and inefficient, being unconsciously affected by their unpleasant surroundings, a condition that tends to undermine their health and reduce their ability to carry on their daily labors. The worth-while employee to-day is inclined to stick where working conditions

Showing contrast between painted and unpainted walls.

are ideal, so better lighting, improved appearance, sanitation and cleanliness make for a saving in labor turnover. Statistics prove that the majority of accidents in industrial plants occur during the darker hours of the day and that the winter months have a greater toll than during the summer period. There seems to be only one logical answer to this fact—inefficient lighting. Nothing is more destructive to the nervous system than overstrain to the eyes and this is particularly emphasized when a person's duties are associated with more or less danger.

Light and Accidents

The relation of light to industrial accidents is covered in the following paragraph, reprinted from Modern Industrial Lighting: "Statistics bearing upon industrial accidents, in which operatives or machinery both suffer, closely parallel the figures touching spoilage. Spoilage, or seconds, may by the critical be said to be due to carelessness, bad feeling among operatives, or a false economy upon the part of employers in entrusting machines and material to ignorant or untrained help. But serious personal accidents have a deeper cause, and when the two forms of accidents are found to increase with the days of diminishing daylight and to decrease as the daylight hours lengthen, it is obvious that light is the factor in reducing both.

"A prominent official of a large manufacturing company is authority for the statement that **'insufficient illumination' is frequently held by juries to be 'contributory negligence,'** and in the defence of accident suits the lawyers of this company make it a point to offer testimony by a competent witness to prove the adequacy of the lighting in this company's plants. The subject is not here considered from any humanitarian standpoint; that is something which each manufacturer must face individually. We simply point out that **each serious accident completely demoralizes a shop**; that this demoralization may last for a day or a week, that during this period of distress and excitement the operatives are inefficient and expectant of further trouble; that production drops; while spoilage and 'seconds' due to nervousness, increase; that the absence of employees is greater and that the whole spirit and morale of the plant is broken down. Facing these facts, we begin to see an economic advantage in accident prevention. As to how to accomplish this most cheaply, the authorities on industrial accidents and safeguards for operatives declare that **good illumination would prevent approximately 25 per cent of the avoidable accidents.**

"Two charts, shown herewith, tell graphically the story of loss and suffering which result from inadequate light. In the one we see the ratio between darkness, cloudiness, and sunlight, while the other shows the 'curve' of fatal industrial accidents of three successive years as reported from a large number of industrial plants."

In analyzing these charts it is clear that the greatest number of accidents occur during the months of diminishing light, and it will be recognized that illumination is sadly under-rated as a means of accident prevention. The use and application of any commodity calls for consideration of proven quality, durability and service. These are the fundamental factors which draw the line between initial saving or low first cost, and true economy.

PROPERTIES OF SEMI-STEEL

We have not read so many complaints during the last year or two about the non-progressiveness of the foundry, says the Engineering World. The fact is that the foundry industry has become very enterprising and has made greater advance since 1914 than almost any other department of engineering. It is not that there is very much that is quite new to record, says the Commonwealth Engineer, but rather that there has been a wonderful development of processes that, while introduced a long time ago, have not until recently been exploited to the fullest extent. Die casting, for instance, is at least 40 years old; the malleable process has been in use for a long time, although less than 200 of our 3,000 foundries produce malleable castings, and America is far ahead of us, and semi-steel which has come into prominence of late has been tried out in many quite small jobbing foundries, admittedly in a haphazard fashion, for many years.

Exact knowledge is indispensable to the successful production of semi-steel, which, taking its qualities into consideration, seems likely to contest the field with malleable iron castings where strength is required at less cost than for steel castings. It is much stronger than cast iron, more homogeneous, therefore less porous, and it offers greater resistance to wear. The mixture may be described as one of 10-25 per cent. of steel added to ordinary grey iron. The very greatest skill in cupola operation is necessary to get good results, and although the Americans have paid greater attention to the metal than we have done, it is being used increasingly for high-class work where sound metal is indispensable. The electric furnace is very valuable in foundries producing semi-steel because scrap can then be successfully used.

With regard to the physical and chemical properties of semi-steel, much depends, of course, on the mixture, but it has been calculated that the strength above that of ordinary iron is from 25 to 60 per cent. Tests have proved that with a 10 per cent. steel mixture the average transverse strength is 2,900 lb., as against 2,252 lb. It has been defined as a decarbonised cast iron. Its composition chemically limits both phosphorus and sulphur to 0.15 per cent. maximum, and the carbon to 3.2 per cent., of which 20 per cent. should be combined carbon.

There is still room for a great deal of experimental and research work on semi-steel.

News From the Welding Field

Autogenous Welding Standards in Railway Practice

General Rules for Using Apparatus—Five Important Factors Are Condition of Surfaces, Bevel and Position of Sheets, Expansion and Contraction, and Proper Filling Metal

By J. M. CALMBACH

BOILER plates cracked through staybolt holes are a common occurrence and are very often very difficult to repair. One method of overcoming this difficulty is illustrated in Fig. 3 in which a new circular section of boiler plate drilled and beveled as shown at the right is applied by welding. It will be noted that the bevels are cut at an angle of 45 degrees and the weld is reinforced by adding 1-16 inch to the thickness of the original plate.

An interesting example of the method of applying mud ring and corner patches is shown in Fig. 4. This operation can be performed either by gas or electric welding, but the caution should be observed of never laying out the patch so that the weld will come lower than between the first and second rows of staybolts above the mud ring.

The method of applying a butt-welded firedoor patch is shown in Fig. 5. The corrugation to allow for expansion is shown and, as in the previous instance, the patch is beveled to an angle of 45 degrees, the well being built up an additional 1-16 inch for reinforcement.

Material prepared by the author and printed in Railway Mechanical Engineer. The first part appeared in August 17 issue.

When constant reworking of tubes and flues has damaged the flue sheet bridges, but the lower portion of the sheet is in good condition, the method of repair by welding in a new top section is shown in Fig. 6. This method effects quite a saving in time since the top flue sheet section can be more quickly laid out and formed, and the labor of cutting and reapplying staybolts in the lower section is eliminated. If any difficulty is experienced in bringing the edges of the new and old plate in alignment previous to welding, a special clamp, as shown in Fig. 7, can be used.

One of the most successful uses of welding in boiler work has been in the application of side sheets and half side sheets. The application of a full side sheet is shown in Fig. 8 with the corrugation for expansion along line A-B.

In making heavy frame welds with gas it is essential that the parts be carefully cleaned and prepared for welding by cutting the ends to the proper angle and making necessary allowance for contraction in cooling. It is also wise, wherever space permits, to build up the weld a certain proportion larger than the original cross section in order to provide additional strength.

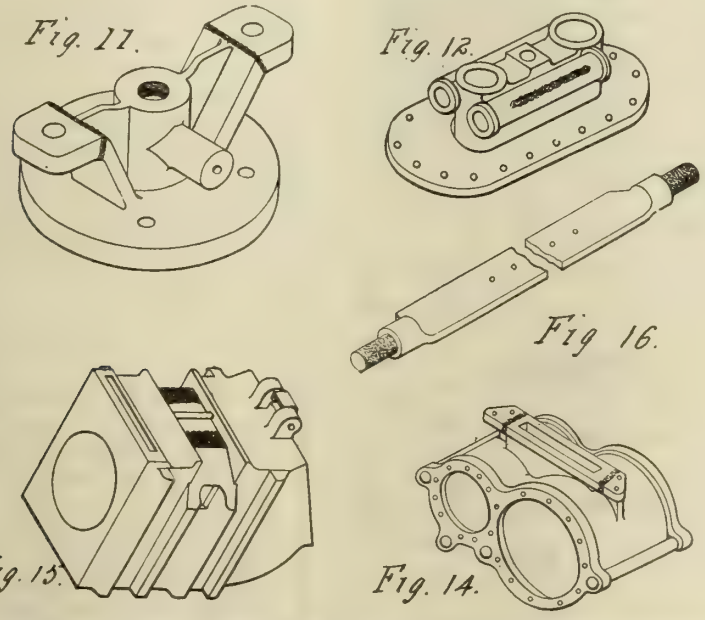

Fig. 11.—Air signal valve casting repaired by gas welding. Fig. 12.—Air compressor steam head reclaimed by gas welding. Fig. 14.—Air cylinder lugs replaced by gas welding. Fig. 15.—Building up worn journal box; gas. Fig. 16.—Building up brake shaft ends; electric.

The standard method of cutting, welding and reinforcing bolsters, truck side and engine frames, and all other steel, iron, or cast steel from ¾ to 8 inches in thickness is shown in Fig. 9 and the accompanying tables. The amount of reinforcement provided is a

Standard Reinforcement for All Heavy Welding

Thickness of Material	Proportional Increase In Thickness
¾ in.—1½ in.	A=25 per cent.
1½ in.—2½ in.	A=15 per cent.
2½ in.—4 in.	A=10 per cent.
4 in.—6 in.	A= 7 per cent.
6 in.—8 in.	A= 5 per cent.

Standard V for Heavy Welding

Thickness of Material	Angle of V
¾ in.—1½ in.	One side—45 deg.
1 in.—2 in.	One side—55 deg.
1 in.—2 in.	Both sides—45 deg.
2 in.—3 in.	One side—50 deg.
2 in.—3 in.	Both sides—55 deg.
3 in.—4 in.	Both sides—55 deg.
4 in.—5 in.	Both sides—55 deg.
5 in.—6 in.	Both sides—55 deg.
6 in.—8 in.	Both sides—55 deg.

The amount of reinforcement provided is a certain proportion of the cross section decreasing in amount as the size of the section increases. It is to be noted from the tables that the angle to which the parts are cut or V-ed varies from 45 deg. to 55 deg.; sections over 2 inches thick being V-ed and welded on both sides.

Preparation for Frame Welding

As in the usual practice the frame to be welded is lined up, trammed and checked with the opposite side as shown in Fig. 10. The weight of the engine is taken off the frame and jacks placed under the jaws on either side of the weld. Then tram over the break, locating permanent points by which the expansion will be governed. Referring to Fig. 10, the frame should be cut out from both sides to the angle shown, all surfaces being chipped and cleaned preparatory to welding. It is necessary to spread the frame a suitable amount to allow for contraction in cooling, this allowance for contraction varying slightly in amount depending upon the location of the break. Referring to Fig. 10, when

breaks occur at points marked A, ¼ inch should be allowed for contraction. At points B 3-16 inch is allowed. Whenever welds are to be made in any part of the jaw the binder should be in place if possible. A ⅜-inch plate should be tacked to the lower side of the frame on which a foundation can be made to start the weld. This plate extends out on both sides of the frame the thickness of the reinforcement and is welded firmly to the frame at all points of contact including the edges. This plate forms a base on which to start the weld.

Two operators should be employed, one on each side of the frame. After the weld reaches the thickness of 2 inches, it should be hammered, this hammering to continue at intervals until the weld is finished. It is important that at no time during the process of the weld any part should be less than red hot. That is to say, the operator should keep the finished part of the weld red hot at all times and when the weld is finished the entire weld should be brought up to an internal stress and decrease the possibility of future breaks. For the amount of reinforcement to be applied reference should be made to Fig. 9 and the accompanying tables.

Miscellaneous Welding and Building Up Jobs

The possible uses of both gas and electric welding in railroad shops are too numerous to mention and both processes have been greatly extended during the past few years, saving large sums of money annually to the railroads. The important point to be remembered, however, is that either welding process costs money and if the locomotive or car part being repaired or reclaimed is small and has a first cost less than the cost of gas or electricity and labor used, it is obviously poor economy to weld it.

For the air signal valve casting, as shown in Fig. 11, however, the cost of labor and gas used in welding on the broken lugs would be considerably less than the cost of a new casting, and it is therefore good economy to make the repair by welding. The castings after being welded by competent operators will be just as good as new.

An interesting example of what can be accomplished with gas welding is shown in Fig. 12. The steam head of the New York air compressor is located at the bottom and, without proper care in draining during the cold weather, will often become cracked through the wall to the exhaust passage as shown in Fig. 12. This steam head is quite an expensive casting with a more or less intricate system of coring in which it was found necessary to maintain walls of equal thickness. The problem in getting a successful weld on this casting is to provide for contraction and this can be accomplished only by the careful and thorough preheating of the steam head after which the crack can be welded with gas. The entire weld and adjoining walls of the casting should be brought to a uniform temperature and allowed to cool slowly

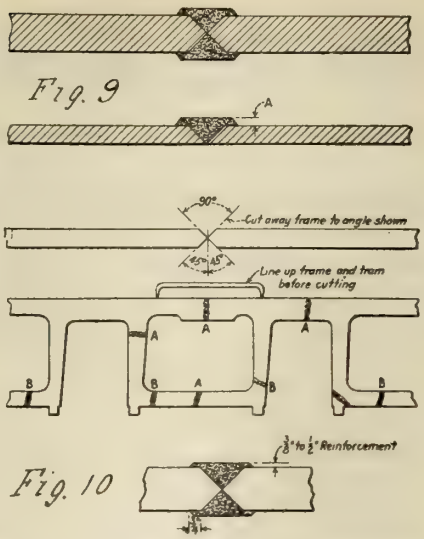

Fig. 9.—Cross section of standard welds showing single and double reinforcements.
Fig. 10.—Location of common frame breaks and method of welding with gas.

to prevent internal strain and a subsequent crack which will be worse than the first.

Building Up Worn Parts

Among the possible uses of the welding processes perhaps none is more important than the building up of worn parts, in many cases making them as good as new for further use. The example shown in Fig. 13 is a worn axle collar before and after being built up by electric welding. After the welding has been completed it is necessary to mount the axle in a lathe and remove excess metal deposited on the collar, leaving a smooth fillet of the original dimensions.

Another example of welding broken lugs is given in Fig. 14 in which both lugs have been broken from an air compressor cylinder, either through a wreck or accidental dropping or mishandling on the floor. The common method of repairing a cylinder with broken lugs is to have new lugs forged of wrought iron or axle steel in the forge shop, fitted to the cylinder which has been properly machined, and secured in place by three or more bolts through the extended sides of the lug and the cylinder. It is obvious

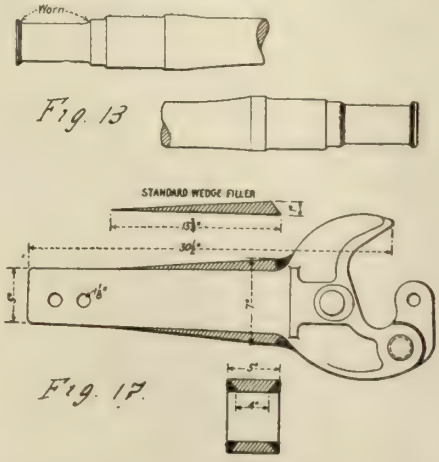

Fig. 13.—Building up axle journals.
Fig. 17.—Adding sectional area to coupler shanks.

that in both cost and length of time required to make a repair, welding is much to be preferred over the mechanical process of applying new lugs.

The method of building up a worn journal box and the ends of an engine brake beam are illustrated in Figs. 15 and 16, respectively. Both of these parts can be built up and made as good as new in a very short time and at a slight cost. In the case of the journal box it is advisable to use gas for building up, but with the brake beam the electric method would be better. In case gas is used to build up the worn brake beam ends, great care must be exercised not to overheat the ends and the entire beam should be carefully annealed before being machined and put back into service. Otherwise there is a good chance of a train delay due to dropping the brake beam.

Another interesting example of welding is shown in Fig. 17 in which a 5 inch by 5 inch coupler is changed to a 5 inch by 7 by the addition of a standard wedge filler held in place by either electric or gas welding as shown in the illustration. One end and both sides of the filler are undercut as shown in the cross sectional view, the undercut space being filled in with welding material, thus holding the wedge filler firmly to the coupler shank. The preceding are but a few of the many interesting examples of welding work performed in modern railroad shops.

ALL-METAL AEROPLANES

There was recently completed in Great Britain the first aeroplane to be made wholly of metal. The advantages of doing away with wood and other combustible material need not be emphasized; and the all-metal aeroplane gives promise of supplanting all the earlier forms. A special alloy of aluminum is used in its construction; and the Government is at present engaged in making very elaborate tests of the strength of every part. Special attention is being given to the risks of corrosion with the metal employed and investigations on this point are being carried out in the Department of Scientific and Industrial Research. So much depends on this new type of aeroplane that although the first flying tests have been very satisfactory the Government prefers to regard the model as an experiment and to suspend judgment until a most exhaustive examination over a long period is completed.

DRILLING UPSIDE DOWN

Mechanics are very apt to dodge a job of drilling from the bottom up, or to go through long processes of disassembling to avoid it. But it may actually be made easier than horizontal drilling or using body pressure for a "down" hole, as the machinist will merely pick up a stray piece of board and use it as a lever.

Practical Ideas From Practical Men

CURVED LINES IN MACHINE DESIGN

John S. Watts

Looking at most of the machinery on the market, one would almost think that the only lines known to machine designers were straight lines and circles, so seldom is it that any curved lines are used, and when a curved line is used it generally has not the graceful appearance it ought to have, but has rather that stiff ungainly form one would expect to find in a child's first attempt at freehand drawing. There are in the mechanical arts a few exceptions to this, such as the automobile, and the ship, but these exceptions simply serve to prove the above statement, as it needs only to be stated to be perceived, that if either of these were made up with such a large percentage of their lines straight ones, as are most other machines, they would not attract the eye by their beauty and fitness, but rather repel as do the straight lined machines.

This state of affairs seems to be due to the ease and accuracy with which straight lined forms can be produced, but at the same time, familiarity with the formation of curves dissipates the fear that most designers have of using them. Lack of practice in drawing curves is the only excuse for not knowing that most forms of curves can be dimensioned and specified on a small scale drawing so that they can be as accurately located and shaped in the full size product as can a straight line. Undoubtedly the curve is more expensive to produce, taking as it does longer to lay out and shape, but as the curved lines can only be desirable on main parts, which are usually castings made from a pattern, which pattern is only made once, and thousands of pieces may be cast from the one pattern, the additional cost becomes the merest trifle when allocated to one machine. When the part to be formed is of steel and is shaped in a die, the same argument applies, that the curved form can be produced to all intents as cheaply as the straight line form.

As against the trifling increase in cost of production, we have a possible saving of material, and we should have a stronger design, with a more esthetic appearance. Touching on this matter of appearance, it is not essential that one should be an artist to be able to produce a pleasing design, for all that is needed to make a machine pleasing to the eye is that all its parts be proportioned and shaped so that they obviously fill their intended purposes without either excess or skimpiness of material. Indeed beauty of outline is, in essence, none other than this skillful proportioning and placing of the material to the best advantage.

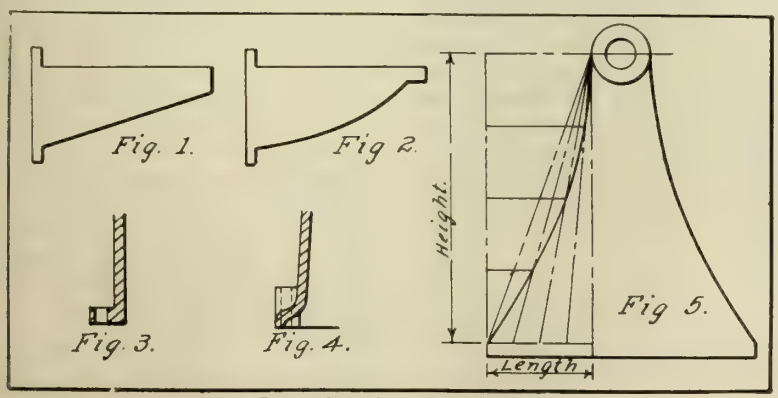
An irregular curve, that is one drawn by freehand and following no exact path, is not possible to reproduce from a drawing with sufficient accuracy for mechanical purposes, but such a curve has no place in a machine whose design is, or ought to be, based upon mathematical calculation. There are, however, plenty of curves, such as the parabolic, elliptical, involute, etc., which follow paths which can be exactly laid out, to fulfil all requirements, and have the additional advantage of being generally more correct as regards strength, etc., than the curve drawn by freehand, or the straight line.

Take for example the case of a bracket cast or bolted to the side of a machine to carry a load as a cantilever. It is all too common to see such a bracket made as shown in Fig. 1. This bracket must, if of uniform width in plan, have unequal strength, that is, there will be a section somewhere in its length, which will be under greater stress than exists at any other section, instead of being as it should under equal stresses throughout its length. The theoretically correct form for such a bracket is as shown in Fig. 2, the lower line being a parabolic curve. A bracket so made is less expensive than the one in Fig. 1, in as much as there will be no need for excess material, as the bracket is of uniform strength and has the added advantage of being more artistic in appearance.

The flanges of bases under machines are often made as shown in Fig. 3, which form has a weak, unsightly appearance, and is in fact either weak or uses more metal than would be used if a better shape such as that shown in Fig. 4 were chosen.

The methods of developing the various curves are given in most engineering text books, and need not be described here, but to illustrate my meaning in stating that a regular curve can be reproduced with accuracy, I show in Fig. 5 a common use for the parabolic curve, and the method of laying it out. The sketch scarcely needs explanation beyond saying that the vertical and horizontal lines are divided into the same number of equal parts, and the curve is drawn through the intersections of the horizontal and diagonal lines. Obviously the curve can be made as accurately as may be desired by using a larger number of divisions. To reproduce the curve in the pattern needs no other dimensions than the length of the base line and the height, therefore the drawing is no more complicated to dimension than if straight lines were used.

The point to be aimed at is to use a curve when it meets the requirements for strength better than a straight line would, and to use that form of curve which is called for, and then the machine will have a pleasing outline. To strive for an artistic effect by using such flowing lines as an artist would in sculpture, will only produce a monstrosity even more hideous than that produced by too rigid an adherence to straight lines, the appearance most desirable being not an artistic one, in the generally accepted meaning of that term, but one of efficiency.



Curved lines in machine design.

IMPROVEMENT TO DRILL PRESS TABLES

By D. A. Hampson

In all shops, there are found one or more upright drill presses of the simple type known as "sensitive" drills. This name has been applied because the design is such that the operator can feel the work the drill is doing and feed accordingly—the feed lever in one hand and the work held by the other combine to secure sensitiveness in the highest degree. Included in this general class are a variety of machines from light bench drills to the most modern design of manufacturing drill weighing half a ton and having a capacity up to nearly an inch in cast iron.

Numerically, the most of these machines are put out with a solid-top flat table. So long as the work pieces or jigs are held in the hand, this solid table

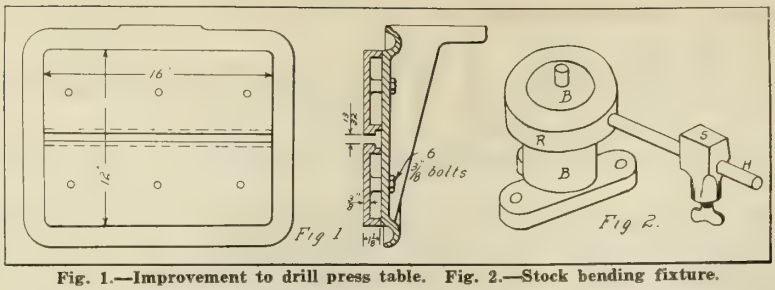


Fig. 1.—Improvement to drill press table. Fig. 2.—Stock bending fixture.

is all that could be asked; it is always ready, a stroke of the hand brushes it off clean, and there is no place for odds and ends to lodge or get mislaid. If the work is heavier, it may be held on with C clamps. The fact that the machine is always ready is a strong argument in favor of the solid table—the drill point may be started on a punch mark, the piece lifted up to get better light on the location, and returned to the table in less time than it takes to tell of it. But sooner or later, it is discovered that this very convenience is really a loser of time.

Fastening work with C clamps is not as quick an operation as it would seem. The average C clamp in the hands of average workmen soon gets "wopper-jawed" so badly that a direct pull is impossible and then the time taken to reset and to knock the work around to align it, or the time spent in trying to find better clamps around the shop may easily run into dollars.

Where manufacturing is done, time is actually saved by fastening the jigs to the table and arranging some other method of getting rid of chips than lifting the jig and dumping it, but the jigs may be small and the table so much larger that some leverage arrangement is necessary in conjunction with the clamps, or the clamps may be in poor shape, with alignment troubles referred to above, or the oil pocket around the edge may interfere with clamping. Then too, the exigencies of orders may call for the shop's entire stock of clamps on a large number of machines at the same time, which temporarily knocks out other work requiring clamps.

As stated, most machines have solid tables—probably because buyers do not realize these points or cannot visualize the growth of their business. Manufacturers do supply tables with a T slot in them but in the smaller capacity machines this is special, and in any case the slotted table carries an extra price, which the buyer cannot "see" at the time. In many shops, these solid tables are drilled for tap bolts and work, or jigs held down by this means. Lack of standardization calls for other holes for each job and soon the table is honeycombed.

A far better method is shown by the drawing. One shop has all their drills so equipped—doing the work on the entire battery of machines at one time reduced the expense considerably and it settled the costly C clamp problem once and for all.

Two castings are required for each machine. Making this false table in two parts saves intricate pattern work and cores and slow T slot cutting. The shape of the pieces is such that a minimum of weight is added to the table but a surface as firm as the original is obtained. Round lugs planed off with the rest support the center and serve for the bolts put in from below. The T slot is formed by corresponding edges which have been easy to machine, as they are plain, outside cuts. When completed, a permanent table—not a makeshift false table—has been obtained, that looks good and is convenient for all classes of work. Existing jigs can usually be re-drilled or are all ready for bolting to a center slot and new jigs can be designed with this improvement in mind.

Some shops have attempted to overcome the shortcomings of the solid table by planing a T slot through it. But because not one table in a score is thick enough for this, the slot has to be so shallow as to be practically worthless and the ledge on top soon crumbles, leaving a ragged hole that cannot well be repaired.

SHOP BENDING FIXTURE

By D. A. H.

Every shop that does manufacturing work has to produce a few trial pieces and do a certain amount of experimental work on flat or round stock formed cold —classed under the general head of "bending." The experimental and special machinery shop takes this for granted and may or may not have provided the best of tools to do this. Hand bending in a vise with the aid of pliers, bits of round and flat steel, a hammer, and punches is slow and awkward—it requires the services of a skilled workman to produce parts that are not all marred up. Where a dozen or a hundred pieces are required, the cost becomes out of all proportion.

Fig. 2 shows a bending fixture that any shop can make for a few dollars. It consists of a base casting B, that has lugs for bolting to the bench; its upper portion is turned to receive a machined ring R, which is made a snug fit but capable of being easily moved by the long handle H, which is a piece of ¾ inch round stock. The top of the base and of the ring are faced off to the same level.

A hole bored in the center of the base permits the insertion of pins, or mandrels, whose projecting end may be round, square, or V-shaped, according to the piece to be formed. The diameter of the upper face of the base is such that it offers plenty of room for screwing fast whatever former or holding block the job may require; the blank being laid in this holding block against the center pin also, is formed by turning the ring R, which is provided with suitable blocks for the purpose. A sliding stop S, on the handle, permits gaging the blank as the first bend is being formed. A little thought applied to the tools and attachments will enable a variety of shapes to be made with a minimum of equipment; and this with but a few holes drilled in the face of the two iron pieces. As new jobs come along, existing tools will be found to be adaptable and tool expense lessens. The great advantage of such a fixture is that parts can be made up immediately that look as good (free from bruises and poor shaped bends), as those turned out by automatic forming machines. The fixture is so simple that it may be made up by an apprentice in spare time.

ROLLERS FOR FINISHED WORK

It is often necessary to move heavy parts along the planer bed and this is done easiest by using rollers to bring the work to the desired position. If the work is finished, as a machine slide, the marks left by rough rollers may be serious. In such a case, lengths of cold drawn steel answer every requirement and ton weights are moved safely with ease.

A new process for using rubber latex in paper manufacture has been invented. It is claimed that it increases the strength and folding qualities of paper, gives it a better texture and greater resistance to water.

IDEAS WANTED.

We are particularly desirous of obtaining for this section of our journal, short instructive ideas. These can cover any phase of machine shop practice and should be illustrated if possible by a sketch of the idea being described.

If you are unable to make a neat sketch, do not let that stop you. Draw the idea as best you can, send it in to us and we will finish it up for you. For all accepted material we pay a good rate, so that not only do you help some one else by passing along the idea, but you benefit yourself as well.

This section should be a regular exchange of ideas. Surely Canadian mechanics have many schemes that have saved them both time and money. Send them to the Editor of Canadian Machinery, 143 University Ave., Toronto, Canada. Don't be a once in a while contributor. Become a regular. You'll find it pays.

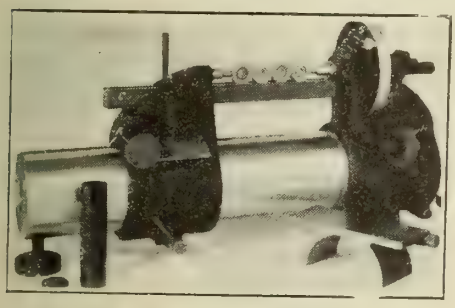
New Things in Shop Equipment

BENCH MEASURING MACHINE

A new bench measuring machine, known as the "super-micrometer" has recently been placed on the market. The machine is illustrated in the accompanying cut. It consists of a rigid cylindrical bed, and a dividing head and adjustable footstock both carrying measuring anvils similar to the standard measuring machine made by this company. The setting of the machine is obtained by the use of standard inch blocks. These standard blocks are machine lapped by a modification of the Hoke process and are accurate within five millionths of an inch.

The screw has a working range of one-half inch, indicated by graduations on a forged Duralumin index wheel and on the measuring spindle. Means are provided to compensate for wear or any slight error in lead, while springs take up back-lash and keep a constant pressure on the thrust bearing.

The footstock is moved into position



Bench Measuring Machine.

along the bed by a rack and pinion and securely clamped into place. A square bar with a channel in one side is provided to hold the standard inches in place during the set-up or to serve as a work rest. This bar passes through the footstock and is mounted on a pin under the measuring spindle as shown in the illustration. It is conveniently stored in a hole in the bed when not in use. Two tables are provided to clamp to the bed for supporting large work. The zero arm, held by friction, is adjustable to position and the knurled knob provides for fine adjustment of the zero line.

The index wheel has 500 divisions 1/32in. wide, each representing a spindle movement of .0001in. These divisions are numbered at thousandths and are direct reading. The index wheel is revolved by a fine round belt, the slipping of which enables the operator to apply the same pressure each time to the measuring anvils. Variations in belt tension do not affect the accuracy of the readings, as the same pressure is applied when setting up to 0 as when measuring the work. The knurled handwheel has two diameters, the smaller for quickly spinning the spindle up to the work and the larger for the final slow movement to the point at which the belt slips. The spindle graduations are .050in. apart with etched figures at each .100in.

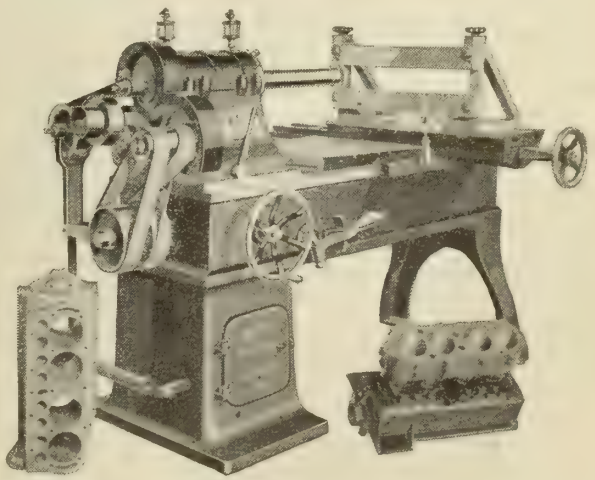
The machine has a range of eight inches between the measuring anvils and 3¼in. between anvils and table. It has a three-point support on the bench. The bed and the supports up to the measuring anvils are unusually rigid, and give a firm definite touch at the instant of contact with the work. Measurements can be repeated within very close limits by the sense of touch alone. The machine is rugged, simple and relatively inexpensive. It is designed for use on the inspector's or toolmaker's bench by any workman of average skill. It is manufactured by the Pratt and Whitney Co. of New York.

3-TON LIFTING-PLATFORM TRUCK

An electric-driven industrial truck in which the frame is made entirely of structural steel hot-riveted in place, has recently been placed on the market. This has proven to be a rigid and durable yet extremely light design of truck. It has a lifting capacity of three tons. The operating mechanism is similar in all respects to other makes of the same trucks manufactured by the Automatic Transportation Co., Buffalo, N. Y.

CYLINDER GRINDING MACHINE

Without an accurate straight smooth cylinder, it is difficult to obtain good compression in a motor, because it is impossible to fit a ring to a cylinder that is not true, or to one that is enlarged at the top, either by wear or by inaccurate machining. The grinder here shown is a development of years of study of this particular subject and several improvements have been incorporated into the original designs. The operating speed of this machine enables a man to grind three Ford blocks in eight hours and grind them right to within .0005 in. of specified size. Larger blocks can be handled at an average speed of from fifty to sixty minutes per cylinder, including set-ups. The frame is of rigid construction and vibration is reduced to a minimum. The machine is of ample range to take the block of any make of car or truck. The bed has a length of 5 ft. and a width of 20½ in. There is a distance of 12 in. from the bed to the centre of the spindle. The carriage has a travel of 26 in., and the range of work includes holes from 2½ to 6 in. in dia. by 16 in. long. Eccentric adjustment has a range from 0 to 1¼ in. The machine requires a motor of 2 h.p., occupies a floor space 5 ft. 3 in. by 3 ft. and weighs about 2,200 lbs. It is manufactured by the Webber Machine Co., Toronto. Ont.



Webber Cylinder Grinding Machine.

END TEST GAUGE

For the testing of micrometers or for the accurate gauging of internal diameters on production work, a special design of test gauge has been developed. The central section is cupped at both ends to receive commercial steel balls 5/16 in. dia., these being retained in position by a cap threaded to screw on the stem. The use of balls for gauge points provides an easy method of compensating for wear, as the balls can be moved slightly to present new places for gauging. New balls can be inserted when others become badly worn. The gauge is known as the "Everwear" and is made in all convenient sizes above 1 in. They are made by the Central Tool Co., Auburn, R. I.

DIMENSION CALCULATOR

Rapid and mechanical addition and subtraction of fractions of an inch, inches and feet, is now possible by means of a calculator recently placed on the market. The front plate carries two circular scales, one divided into 48 equal parts, and the other circle graduated into sixty-fourths. The former is used for calculations where operations involve integers of feet and

inches, and the finer scale for calculating fractions of the inch. Black figures running in clock-wise sequence are used for addition and red figures in counter-clockwise for subtraction. Mounted within each of these scales is a circular, movable disc graduated on its periphery with graduations and figures corresponding on the scale. A pinion on the shaft of each disc meshes with a gear carrying the circular scale at the top of the device. The perforations on the rotary discs are used for the insertion of a stylus.

When commencing to use the device the gears are disengaged and the dials set at zero. The different values are added or subtracted by turning the respective dials to the desired positions, in consecutive order. Calculations are always started with the disc zero mark placed opposite that of the scale. A complete revolution of the upper gear is indicated by means of a buzzer. The result is read direct from the different gears and discs. The device is made by W. Teinert, 410 West 23rd St., New York City.

INTERNAL CYLINDER GRINDING MACHINE

A new type of grinding machine has recently been introduced from Europe that differs considerably from those generally used here at present. The principal features are the capacity for a large range of sizes and the arrangement of the grinding head and work table. In most small cylinder grinding machines the grinding head remains stationary while the work table moves back and forth. In this imported design the work remains stationary while the head is given a reciprocating movement, this being carried on automatically. The grinding spindle rotates about its own axis and also revolves around a second axis parallel to its own, the eccentricity of the two axes being adjusted automatically or by hand. Several spindles are provided for a varied range of work, these spindles being mounted in bronze bushings and ball bearings. To assure the work table being absolutely true, it is finished by grinding after mounting on the machine. It is accurately adjustable, both vertically and horizontally. An exhaust fan fitted with a flexible hose is part of the tool equipment. The large machines are provided with a grinding head movement of 106 in. and all machines have a lateral adjustment of 15¾ in.

The small machine requires 4 h.p. to operate while 25 h.p. is necessary for the heavy grinder. The respective weights are 3,750 and 70,000 lbs. These machines are being marketed by Marburg Bros., of New York.

PIPE WRENCH

A pipe wrench that is simply constructed, light in weight and having great strength, has recently made its appearance on the market. The tool is known as the "Little Giant" and is of the end opening type, which design enables it to be fitted to pipes that would be difficult to work on with side openings. The handle is drop-forged and heat treated, the double central jaw being integral with the handle. The moveable jaw is likewise drop forged and heat treated, while the adjusting nut is of hardened steel. It is claimed that the wrench grips and releases freely in all positions. The moveable jaw may be inserted from either side, the double feature of the fixed jaw adding to the life of the tool. The tool, which is made in 8, 10 14, 18 and 24 in. sizes, is being placed on the market by the Greenfield Tap and Die Corp., Greenfield, Mass.

PISTOL-GRIP HACKSAW FRAME

A pistol-grip hacksaw frame has recently been offered to the trade. Springs are used to provide constant tension on the blade. This feature enables the

Pistol-grip Hacksaw Frame.

blades to be changed quickly. The adjusting pawl is set down inside the frame as low as possible. Strong but light steel tubing is used for the back and all steel parts are nickel-plated. The blade may be set to cut in any one of four directions by means of the wing nut. The frame is 3⅜in. deep and blades of from 8 to 12in. may be used. The hard rubber, checked handle provides plenty of finger room and gives a comfortable grip for the operator. These frames are made by the L. S. Starrett Co., Athol, Mass.

POWER CLAMPING DEVICE

In order to provide clamping facilities to the column of a radial drilling machine when the operator is standing in a working position, there has been developed a device for clamping by power. The clamp is controlled from the head and no air pressure is required. The air pressure is driven from the main vertical driving shaft which extends through the box at the rear of the column. By means of two friction clutches the screw may be operated in either direction. The friction clutches are engaged by the action of a cam operated by the screw. The clamping mechanism is controlled by a set of links and the hand lever under the head. Friction clutches are self-releasing and slip at either end of the movement of the tightening lever, thus protecting the parts from injury. These devices are being installed by the Drises Machine Tool Co., of Cincinnati, Ohio.

HYDRAULIC FLANGING PRESS

An exceptional large hydraulic flanging press, designed for the flanging of plates for car ends, has recently been constructed. The machine has a capacity of flanging cold steel plate 5/16 in. thick by 10 ft. in length. Two rams the used, one located at the top of each side housing, the main cylinders being 20 in. dia.; auxiliary cylinders of 5½ in. dia. are used for returning platen to upper position. The ram has a stroke of 24 in. and the maximum distance between the platens is 36 in. The press is capable of exerting a pressure of 435 tons. All the main castings are made of cast steel to withstand the heavy pressure. The machine weighs approximately 42 tons. All movements of the press are obtained by the operation of one hand lever controlling a three way, poppet-type, high-pressure valve. This press was made by the Hydraulic Press Manufacturing Co., Mount Gilead, Ohio.

VISE JAW CLAMPS

A set of vise jaw clamps specially designed for use in bench vises or in vise jaws or clamps mounted on milling machines, surface grinders and similar tools, has recently been placed on the market. Each pair of the set has different sizes of holes, for either square or round stock, so that various sizes of finished stock can be held without marring the surface, when slotting, milling, grinding, threading or other operations are being performed. The two sections of jaw are forced apart when vise is released by action of two springs. Clamps are hardened and ground all over. They are designed to take stock from 1-8 to ½ in. in size. They are manufactured by the Milliken Machine Co., West Newton, Mass.

11-INCH SLIDE REST

A slide rest especially designed for use on lathes has recently been offered to the trade. A feature of this rest is the method of securing the rest to the base. A tapered hub on the rest fits in a tapered hole in the base, and the clamping is obtained by action of a sliding segment controlled by two collar screws. The feed screws have 10-pitch square threads. The swivel is graduated and a standard toolpost is provided. All bearings are accurately finished. The travel is 5¾ in. by 2½ in. This rest has been brought out by the Milliken Machine Co., West Newton, Mass.

For anyone wishing to secure a fuller knowledge of the construction of a vacuum tube the A. B. C. of Vacuum Tubes Used in Radio Reception, by E. H. Lewis, A. I. R. E., will serve the purpose ideally. It is especially valuable to the person who knows nothing about radio and very little about electricity, as no previous technical knowledge is necessary. Starting with an explanation of elementary electrical terms, and list of symbols, the functioning of various vacuum tubes as detectors and amplifiers is explained step by step in an easily understandable manner. Speech distortion is discussed and its elimination pointed out. This is one of the recent books issued on this subject by the Norman W. Henley Publishing Co. Price $1.00.

To Visit Busy North

THAT A party of manufacturers, representing Toronto Board of Trade will leave shortly to inspect the lumbering and mining regions of Northern Ontario indicates an appreciation of the steadily increasing business from those industries, and a desire to learn their requirements at first hand with the idea of most efficient service.

Developments in the Ontario gold mining region alone are now well beyond the infancy stage and production is such as to invite, if not challenge, world comparison. Two years ago, when activities were not attracting the attention that they are to-day, the amount paid by the mining industry in wages was well over twenty-five millions. Machine drills and parts were purchased to the value of over seven hundred thousand, while for drill steel more than half a million dollars were expended. These amounts, however, but serve to indicate the extent of the outlay for equipment of all kinds. New mines are being placed in operation, vast areas are under prospect, and the field is one of great possibility for the Canadian manufacturer and workman.

Growing Interest in Standards

MARKED progress in being made in standardizing work within Canada, and also in an international way. Co-operation among manufacturers and engineers in this matter is recognized as an absolute essential in order to guard against what are termed "individual divergencies" whereby many unnecessary varieties of parts are produced regardless of the great economic value of comparison and adoption of standard dimensions. The movement is not one that has to do with revelations of secrets, but with co-ordination in parts and products for certain operations or purposes on which superficially distinctive features perform no useful purposes. The requirements not only of domestic industry but also those of export and import business have to be considered.

Word comes from Germany that there has been great concentration on standard systems in that country. In fact an American engineer recently returned believes the time is not far distant when manufacturers on this continent will receive inquiries from many foreign countries to furnish goods according to German national standards. He points out that one of the main reasons why forward-looking Germans force their standardization work is because they want to introduce German standards in the great importing countries, and possibly in the whole world. Holland, Switzerland, Austria, Sweden and many other European countries follow the German lead very closely. In his opinion the great German deliveries in kind to France will no doubt be made as far as feasible according to German standards, thereby introducing them in that country. This enthusiasm is due to a more or less general recognition, created under the pressure of war conditions, of the great economic value of standardization, and to the very generally accepted opinion that a standardized industry would be one of the strongest weapons in Germany's stuggle for economic rehabilitation and financial reconstruction.

It is noteworthy that Canadian manufacturers are showing a keen interest in this work. England is realizing fully the importance of her standards and is promoting their recognition in the different parts of the empire.

British Want the Business

A RECENT British export journal discusses trade relations with Canada under the somewhat lugubrious caption: "Canada: British or ——? Customs reductions which please Dominion protectionists and U. S. A. tariff wall climbers." It deplores the fact that while British goods were bought to the amount of about twenty-five million pounds, American goods to the amount of one hundred and thirteen million pounds were purchased by Canadians. Then the journal proceeds towards the solution of the proposition. It points out that the Fordney tariff wall cannot but cause a slackening in business between the two countries; it does not deny that Canada requires British goods, and further considers as an encouraging factor the evidence of the British preference by the Fielding tariff and eventually asks whether the cause of the trouble may not be too great reliance on preferences and too little initiative in studying the requirements of the Canadian markets.

It must appear to our British friends that the great amount of American capital invested in Canadian industry, the geographical advantages, the fact that large American houses, whether represented in Canada by a branch factory or not, regard Canada as a definite field for direct business, requiring aggressive advertising and a service in every way as considerate and efficient as that which they give their home market—that all this must explain a certain amount of the difference in Canadian trade going to the two countries. To a remarkable extent, British manufacturers are recognizing the increasing importance of the Canadian market, and Canadian branches and Canadian representatives are making their appearance in increasing numbers. There is a decided preference here for many British lines and there is no reason why these lines should not be considerably extended. The journal concludes with this sound observation: "With adequate and enterprising propaganda, the establishment of local stocks in the Dominion, and the employment of suitable agents to do the business, there is no reason why Great Britain should not obtain a very much larger share of Canadian trade than is the case at present."

Pig Iron on Canadian Metal Market May go to $45

Advancing Coal Prices Add to Problems of Production—Pittsburgh Blames Rapacity of Labor—Predicts Economic Break—Canadian Mill Announces $39.30 Rate on Spot Pig—Montreal Market Reports Buying Curtailed

METAL DEALERS EXPECT RADICAL PRICE CHANGES

WHILE it is a fact that a few months ago the steel and iron trade thought it good for business to resist any influence that made for inflation in places, to-day it is evident such a movement is receiving some encouragement. This, it is claimed, is one result of the attitude represented by the concession to striking coal miners by the operators, a concession for which the public must pay. Advices from Pittsburgh declare that banking interests have practically acquiesced in a drifting policy until such a time as mounting production costs, to which labor demands are declared to be contributing unreasonably, must reach the breaking point and economic law brings about the inevitable remedy. This is actually reflected in the market to-day when difficulties of delivery, and uncertainties of price make for unsettled conditions.

More significance than was at first looked for seems to attach to the advance of 20 per cent. in wages by the United States Steel Corporation for it was shown that stability had been in evidence up to the present time. Coal costs must soar with the reinstatement of the 1920 wage scale, and it is this factor that has to be considered together with the possibilities of labor troubles in the steel industry. Authorities declare that such prices as are predicted cannot last indefinitely, that high wage rates, shortage of materials and transportation must bring about a crisis some time in 1923, and that stern lessons in economics are going to be taught in the readjusting process.

In the Canadian market to-day $45 pig iron is the prediction for the not-far-distant future. In fact Algoma Steel is quoting $39.30 for spot, a somewhat nominal price as there is not a great quantity available for immediate delivery. Domestic supplies on contract basis are shrinking and foundries entering the market are confronted by conditions that recall war-time problems. Canadian furnaces are confronted by the advanced coal costs, by stiffening, if not increased, wage rates, and the outlook is one that indicates a general upheaval in prices of steel and iron and their products.

As announced in last week's market reports, steel pipe prices have at last succumbed to the upward movement. Manufacturers at distance from sources of raw material are laboring under considerable difficulty in securing supplies of skelp. These are the days when the car scout has to be particularly keen, with mills on one hand consuming carloads per day, and on the other hand, with transportation beset by many uncertainties. Advances in prices all along the line have at last brought an increase, declared by some to be overdue, of $6 per ton on black piping and $4 per ton on galvanized.

Some steel companies in Pittsburgh and district have withdrawn all prices and a radical upward revision in lists may be expected. Commenting on Canadian conditions the sales manager of a large corporation observes: "They are undoubtedly improving, and we look for good business in the near future; in fact it would not be at all surprising if a distinct shortage of all steel products will have to be faced shortly. Unfortunately coal conditions are such as will not likely permit of reasonably satisfactory operations for some time to come."

Montreal markets show a slowing up that is quite suggestive of the holiday season, with this difference, that the condition cannot be attributed to that cause. Strike influences are apparent, and demand during the past week has fallen off. Quotations are swinging upward, and there appears to be curtailment of consumption, for the market is not taking kindly to speculative factors which are the usual development of protracted strikes. The policy of watchful waiting seems to be preferred by some, and this would indicate that demands of business are not so insistent in some quarters as to consider premium prices favorably. Even the quotations on Summerlee imported pig have advanced to $33 dock, and $38.50 in lots of five tons or more, warehouse. Some foundries are already in the market. There is little change in the non-ferrous section, but some interest is being shown in cast iron scrap, which is none too plentiful.

Toronto

August 30.

TORONTO markets still report good enquiry in spite of the upward trend of prices. There is no tendency to encourage sensational movement and it is remarkable that quotations in certain departments show slight differences of opinion. This is regarded as indication that some warehouses have far larger stocks available than generally supposed. Difficulties of supply are manifesting themselves more widely, and conditions that made for scarcity in sheets, are now manifesting themselves in other sections. Pig iron, naturally the basic factor, serves to illustrate most strikingly the problems of the situation. Domestic producers are not in position to deal with the situation and quotations are largely nominal. Algoma's spot price is 39.30, and it is predicted that $45 pig is not altogether out of the question.

Scrap metal markets are quiet, with some enquiry for aluminum, lead and zinc, the natural result of activities in the motor car and building industries. Some enquiry has developed for cast iron scrap but very little is available. Current prices follow:

Copper, light ..... per 100 lbs.	8 50
Copper, crucible	11 00
Copper, heavy	11 00
Copper Wire	11 00
No. 1 compositon	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	4 85
Light brass	4 00
Medium brass	5 50
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton.	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine cast iron	20 00
Pipe, wrought	7 00

Non-ferrous metal markets continue to be more or less featureless. Tin is described as weak, copper as easy, lead firm, zinc firm, antimony steady and aluminum steady. In connection with the tin market it is announced that the Canadian government merchant marine announces a fortnightly service to Swansea and Cardiff, instead of the regular monthly sailings. It will carry greatly increased exports from tin plate from South Wales and imports of Canadian goods. British tin plate manufacturers, it is claimed, are ousting United States producers from the Canadian market. Current prices:

Lake copper	17 25
Electrolytic copper	17 00
Castings, copper	17 00
Tin	36 50
Solder	8 00
Lead	7 00
Antimony	7 40
Aluminum	22 00

Sheets, bars and plates continue to play an active part in the demand with prices showing strength and the supply more or less problematical and specific requirements. Current prices:

Iron bars	3 25	3 40
Steel bars	3 25	3 40
Reinforcing bars	3 25	3 40
Steel hoops		4 25
Tire Steel		3 40
Spring steel		7 00
Band steel, No. 10 gauge and 3-16 in base	3 65	3 75
Small shapes		3 40
Sheets, black, No. 28		5 40
Sheets, blue ann., No. 10		4 25
Canada plates, dull, 52 sheets		5 75
Canada plates, all bright		6 00
Galvanized Sheets, No. 28.....		6 85

Demand for machine tools continues

to be somewhat spotty. Some orders are being placed for fairly large pieces, but this business as a rule is the reward of aggressive salesmanship. The horizon, however, is said to be lifting and the last quarter should show improvement.

Owing to increased cost in production the Landis Tool Company has found it necessary to advance prices ten (10) per cent. on all machines and machine parts. These prices were effective August 15th, 1922.

Upward revision of boiler tube prices is in immediate prospect. Reports are being received from Pittsburgh and other sources that prices for the time being had been withdrawn pending issuance of a new list.

Montreal

August 30.

THE PAST week has seen business in the iron and steel lines fall off to a very great extent. July and August are always considered as quiet months, but this year the volume of business did not contract until after the middle of July. From then on to the past week, conditions were only fair, and the further curtailment of the past week has brought business, in these lines, back to the point where it was a year ago.

The strike situations are having a very direct influence on business. Consumers of iron and steel have not come into the market as freely as they otherwise would have. The producers of pig iron, the steel mills and jobbers all feel that deliveries and prices on material for the last quarter will be largely speculative. Pig iron has advanced so also has steel. It is felt that these higher prices are only the advance notices of still higher quotations. The machine tool business is quiet but supplies are moving fairly well. The nonferrous metals are quiet, which condition also describes the scrap metal market.

Iron and Steel: The demand for iron and steel has been very light during the week. The unusual conditions, however, have been such as to bring increased quotations. The steel mills are now quoting $2.60 base, to the large consumer, which is an advance of ten cents. Heretofore contractors have been on the list of the large consumers. During the week they have been put on the jobbers' list which carries a quotation of $2.70 base. Contractors' requirements are so diversified that it was felt that with the former arrangement an injustice was being done the jobber who bought not only more consistently, but usually had a more desirable specification. Thus contractors have had the price of steel to them advanced twenty cents, the large consumer was advanced ten cents and the jobbers' figures remain unchanged.

Hard steel reinforcing bars are quoted at $2.40 base to the contractor and jobber, with a regular list of extras for size and a list of extras for bending. The action of the United States Steel Corp. and other large steel industries in the United States advancing wages 20 per cent. during the week means, eventually, higher steel quotations. There is a real labor shortage in the American mills, which were operating at about 70 per cent. of capacity. The railways have been heavy purchasers of steel as well as the automobile and agricultural interests.

The demand for merchant bars, structural steel, reinforcing bars, and plates has been very light locally. Small steel products are moving well, as also are sheets. One jobber reports that in spite of weekly replenishments to stock he has not been able to get into his warehouse any 26 or 28 gauge galvanized sheets. The trade in miscellaneous products is spotty, the total volume being somewhat less than that of last week. Local quotations are as follows:

Iron bars, base	3 15 to 3 25
Steel bars, base	3 15 to 3 25
Reinforcing bars, base	3 15 to 3 25
Steel hoops	4 25
Tire steel	3 25 to 3 40
Spring steel	7 00
Band steel, No. 10 gauge and 3-16" base	3 65 3 75
Small shapes	.... 3 40
Sheets, black, No. 28	.... 4 40
Sheets, blue ann., No. 10	.... 4 05
Canada plates, dull, 52 sheets	.... 5 50
Canada Plates, all bright	.... 7 00
Galvanized Sheets, No. 28	.... 6 50

Pig Iron: Canadian furnaces have temporarily withdrawn quotations from the local market. The nominal quotation on No. 1 iron is $36.80 car load lots on tracks. Summerlee quotations are advanced to $33.00 for car load lots on dock Montreal, and $38.50 for lots of five tons or more ex warehouse. Owing to the inability of local sales offices of Canadian furnaces to take on increased bookings, local requirements are being taken care of with Summerlee which is the only imported iron actually on the local market at the moment. A shipment of Carron iron is en route here, but is not, of course, available. The exact figure that will be asked for this iron is not definitely known. It is reported that only one furnace from the Buffalo district is quoting iron locally, others are short of coal. Until conditions improve, and coal is available, there will be little change at the furnaces. Supplies of pig are being consumed daily and some foundries are already in the market. Others will follow and it seems reasonable to expect that all the present supplies of Scotch iron will be consumed, before the atmosphere clears. Most local dealers have but little to say, their policy being one of watchful waiting. Local pig iron prices follow:

Algoma, No. 1, car lots on tracks, nominal quotation	36 80	....
Summerlee, 5-ton lots, warehouse	38 50	33 00
Summerlee, 30-ton lots, dock	33 00	....

Machine Tools and Shop Supplies: There has been little change in the machine tool situation. During the late spring and early summer a few small sales were made. This business has fallen off recently. There is practically no demand for iron working tools, and only a small demand for woodworking tools. The supply end of the business continues at about the same volume as last week. No important changes in quotations have been announced during the week. Inquiries for supplies are improving and it is felt that September promises to be a distinct improvement over August.

Non-ferrous Metals: Business was rather quiet during the week. For some weeks past, only a nominal volume of business has been done. Last week was about the average. Orders are small and widely distributed. Tin and antimony quotations each weakened a quarter of a cent. Other quotations remained stationary. Local quotations are as follows:

Lake Copper	17 75
Electrolytic Copper	17 50
Castings, Copper	17 25
Tin	35 00
Lead	7 00
Spelter	8 75
Antimony	6 25
Aluminum	22 00

Scrap Metals: There have been a few more inquiries for scrap material and some sales of iron and steel scrap have been made. Prices remain about the same, as have been prevailing for some weeks. There appears to be little desire to increase holdings locally. Foundries are manifesting a little more interest in scrap iron as the temporary conditions surrounding the pig iron market, together with the gradual improvement in conditions, have turned their attention to their supply of iron. Local quotations are as follows:

Copper, light per 100 lbs.	8 50
Copper, crucible	11 00
Copper, heavy	11 00
Copper Wire	11 00
No. 1 composition	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 00
Light brass	4 00
Medium brass	5 50
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine cast iron	20 00
Pipe, wrought	7 00

Pittsburg

August 30

THE PAST week has been the most important one in iron and steel trade developments for a year if not for several years. In a nutshell, the trade has joined the inflationary movement that has been asserting itself in some lines for several months, and it goes farther, in that it will push inflation instead of resisting, as it was doing vigorously only two months ago.

The cause of the change in attitude is the rapacity of labor. It is necessary to be frank in order to give the news. It has been decided, with the advice of banking interests, to go with the tide, letting the unreasonable demands of labor work out into higher

costs until the inevitable break, dictated by economic laws, is precipitated.

Coal mining costs are outrageously high, by the re-establishment of the 1920 wage scale, and the scarcity produced by a five months' strike is such that coal will command tremendous prices right into, if not through the winter. Unwillingness on the part of building trades labor to do a reasonable amount of work has brought fancy wage rates in building operations, even in some cases for common labor, and the steel industry has been unable to stand the competition, hence it raises its wages to a level not warranted by economic conditions.

The costs of producing pig iron and steel will be very high by the double influence of high wage rates and shortage of materials and transportation. Instead of the steel industry drawing upon its surplus to pay the difference between old low-priced contracts still to be filled and the high costs under which the orders must be filled it will advance prices to the possible limit to make profits out of steel the consuming industries are still willing to buy. This will be a year of very moderate profits for the producers, but a year ending with prices that cannot last indefinitely. When the end comes, some time in 1923, lessons in economics will be taught labor in the hard school of adversity.

Connellsville Wages

The H. C. Frick Coke Company, the fuel subsidiary of the United States Steel Corporation, posted notices in the Connellsville region that it would revert to the wage scale of September 1, 1920, the highest scale ever paid in the region, and independents promptly followed. There was no offer of union recognition. The region has been strictly non-union for more than 30 years but the United Mine Workers, in connection with their general strike inaugurated April 1 last, organized the men to an extent. The notices were posted four days ago, but up to this writing only a few men have gone back to work, just as men were straggling back from time to time previously. The Frick Company had built up a moderate production of coke, but was shipping very little coal to the corporation's mills and by-product ovens, compared with normal. Independents have been operating very poorly. The members of the Pittsburgh Coal Producers' Association, which have had a regular union strike on their hands, offer the men the 1920 scale but without the check-off, which means without union recognition, and the strikers have failed to go back. In various other districts the operators have yielded, having suffered a defeat that was unimaginable last March.

The United States Steel Corporation announced that, effective September 1, it would advance wages at its mills and furnaces 20 per cent. Some independents followed almost instantly with announcements, and the advance will no doubt be complete. For the central west, Pittsburgh, Wheeling, the valleys, the Lake Erie front, Chicago, etc., this means an advance in common labor from 30 to 36 cents an hour. The pre-war rate, set by the advance of February 1, 1913, was about 19 cents, while in 1898 the usual rate had been 13 cents. In 1898 bars, shapes and plates sold down to a cent a pound. Now wages are practically tripled and freight rates are much higher. According to the Connellsville Courier the average value of Connellsville coke in 1894 was $1.00, and in 1898 $1.55. Now $11.50 is quoted and blast furnaces assert they will not buy until the price gets down to $7.00. Competition among merchant furnaces to get coke and be the first to resume will probably result in more than $8.00 being paid, when the time comes that coke is offered in sufficient volume to enable any furnace to run. To date, as indicated above, the offerings are too small to make it worth while to try to buy, in such tonnages as a blast furance must have.

Steel Price Advances

On August 15, independent pipe mills advanced their prices three points (a point is about $2 a net ton) on black and two points on galvanized steel pipe. Eight days later than these announcements, and one day after the Steel Corporation had announced its 20 per cent. wage advance for mills and furnaces and the advance of 40 per cent. or more in the Connellsville region, the National Tube Company, the pipe subsidiary of the corporation, announced an advance equal to that of the independents.

A fortnight ago the American Sheet & Tin Plate Company advanced its price $2 a ton on blue annealed and $4 a ton on black, galvanized and automobile sheets, to levels independents had previously been securing. Now the independents are advancing to a level $3 above the corporation prices. The market is thus quotable at 3.35c to 3.50c for common black.

The Carnegie Steel Company has withdrawn practically all prices. It had been selling bars, shapes and plates, for altogether indefinite delivery, at 1.80c. It is reported that some purchases might be made from it at 1.90c for bars and 2.00c for plates and shapes, but the company will not admit having these or any other prices. Independents generally are asking 2.25c, and obtaining the price without difficulty on anything like early delivery.

Connellsville coke has been declining and has reached $13 on foundry and $11.50 on furnace, the latter price not interesting furnaces.

The pig iron market is one for prompt shipment out of stock only. Neither producers nor consumers are disposed to consider forward deliveries. Producers do not know when they will again be able to make iron. There is no more valley foundry iron offered, and apparently the point nearest Pittsburgh from which any foundry iron can be had is Buffalo, at say $32, Buffalo furnace, making a price delivered to Pittsburgh equivalent to $33.50, valley basis, allowing for freights. A week ago the market was quotable at $30, two weeks ago at $28 and five months ago at $19. Over 2,000 tons of Bessemer iron have been picked up at $30, a $3 advance in the week, and it is thought this took all the iron to be found. Last sales of basic seem to have been at $26, valley, some time ago. Now there are no offerings but it is claimed $33 was bid.

ANTICIPATES LABOR SHORTAGE

One reason said to be behind the recent increase of 20 per cent. to employees of the U. S. Steel Corporation, is that the immigration law has cut off the supply of unskilled laborers which formerly drifted to the iron and steel centers.

Resumption of coal mining and the increasing demand for laborers in other industries, combined with the expected business revival this fall, is reported to have caused apprehension among mill managers, who feared that the higher wages elsewhere would cause sufficient desertions to hamper their operations.

The United States Steel Corporation employs approximately 220,000 men, of whom 156,000 are affected by the wage increase, the 64,000 in the mining and transportation departments being excluded. The increase will swell the company's pay roll by $35,000,000 on the basis of "full time." The increase will bring the rate for day labor up to 36 cents an hour. The present rate is 30 cents an hour.

A CONCESSION TO HOME INVESTORS

In offering to renew the five and a-half per cent. Canadian Government bonds maturing December 1st at the same rate of interest as is carried by the maturing bonds, and allowing a bonus of one month's interest, the Minister of Finance is making a material concession to the Canadian investor, as this rate is higher than was paid on the recent Canadian loan in New York. The high class of the security, which is the very best that can be offered in Canada, and the liberal rate of interest should lead to large investment in these Dominion bonds. Attention is directed to the official advertisement giving details.

BRITISH ELECTRIC SHIPS

Three vessels of a very unusual character are shortly to be built in a British shipbuilding yard. Each will be about four thousand tons and especially designed for the fruit carrying trade. They will be fitted with oil engines of a special type designed in this particular yard and recently tested under ocean-going conditions with most satisfactory results. The engines will drive electric generators which will supply current to electric motors placed on short propeller shafts at the stern of the vessel.

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

PIG IRON

Toronto price:—

Silicon, 2.25% to 2.75%	35 65
Algoma, No. 1, Montreal,	36 80
Summerlee, Scotch, Montreal dock,	32.50
Summerlee, Warehouse, 5-ton,	37.50
Carron, Montreal docks	32.50
Grey forge Pittsburgh	34 76
Lake Superior, charcoal. Chicago	34 65
Standard low phos., Philadelphia	35 00

News From the Industrial Field

C. Victor Grantham, is the Wallace Barnes Co.'s representative in their booth in Industrial building, Toronto Exhibition. It is an interesting display of wire and steel springs.

Quebec.—The announcement was made on August 22 that ten new double truck cars were to be placed in operation within a week on the city lines of the Quebec Railway, Light, Heat and Power Co. The company is now operating thirty-seven large cars on these lines, which means that the old model cars will disappear entirely this autumn.

When freight shed No. 3 of the C. P. R. was destroyed by fire at Fort William, between 25 and 30 box cars were lost and a large quantity of merchandise. A nearby wharf was destroyed and the bow of the steamer Kenora was damaged. The shed contained 7,000 bags of cement, 1,000 tons of nails, several hundred tons of binder twine and some iron pipe. The total loss will be about $175,000.

Yarmouth, N. S.—The town council on August 21 decided to place an order for 3,000 tons of Welsh anthracite coal. The coal is available at a British channel port. The cargo will be ready for shipment early in September. It is planned to use the coal for heating the public buildings, hospitals and churches of the town. If after these requirements are taken care of there is any balance it will be sold to private citizens at cost.

Sherbrooke, P. Q.—The city council has made arrangements with the coal dealers of this city to obtain a limited supply of Welsh anthracite coal which, it is expected, will be delivered about the first of September. The coal contracted for will be in two sizes, lump and nut, and it is estimated that it can be retailed for $22.00 a ton. It is understood that this coal is being delivered at Montreal for a price of $12.00 a ton f.o.b. cars.

Sherbrooke, P. Q.—During the past few days a new Sherbrooke industry has been established. It will be known as the Manganese and Steel Foundry Ltd. and is located on Water St. The company will produce all types of steel castings. The premises occupied were formerly known as the Sherbrooke Iron Works. The capacity of the steel furnace is one ton at a heat, but three heats a day can be run. The company has several very nice initial orders on its books, and prospects for a capacity business appear to be good. P. McCullough, formerly of the Canadian Brakeshoe Co., is president and general manager, while A. S. Bayles, formerly with the Canadian Ingersoll Rand Co., is secretary-treasurer.

Five steel bridges representing the completion of the Toronto-Hamilton highway entrance to Hamilton, and also a link in the Niagara-Hamilton road were opened Wednesday, August 23, by appropriate ceremony. The actual expenditure on this work was $656,000.

The Morse Chain Co. of Ithaca, N. Y., have found it necessary to acquire larger and more desirable offices in Philadelphia. They have recently moved to 612 Franklin Trust Bldg., 18-22 South 15th St. J. A. Meaney will continue to be manager of the Philadelphia district.

Reports from Edmonton indicate that, even with a fair average crop in prospect the farmers cannot quite relieve their minds of possibilities of frost and hail and the continuation of wet weather, which in many districts has seriously delayed operations. Crops which were sown late are likely to yield particularly well. On the other hand, grains which were sown earlier were light and below an average crop. Pasture, late oats and potatoes have benefited immensely from the late rains. Many reports indicate that crops will exceed earlier forecasts.

Ed. Logan, their factory representative, is in charge of the booth of the Clipper Belt Lacer Company, of Grand Rapids, Mich., at Toronto Exhibition. The line consists of belt lacers, steel belt hooks, also twisted rawhide and waterproof fibre pins. The company has recently perfected a rustproof hook for use in damp places, such as laundries, mines, chemical plants or wherever rustproof hooks are required. A moving belt display, entirely of aluminum, is a feature. All moving parts run on ball bearings, making it practically noiseless.

The Anaconda American Brass Company, with headquarters at Waterbury, Conn., has taken over the plant and goodwill of Brown's Copper and Brass Rolling Mills at New Toronto. It is expected that the plant will resume operations about Sept. 1, with a force of two hundred and fifty. For the present no change will be made in the product of this plant, but future plans may include the addition of other lines and the extension of the plant.

It is thus that another large American industry finds location in Canada. The report that the plant is to be moved to Port Credit or that the Canadian headquarters of the company will be located there is contradicted. To Reeve Parkinson, of Port Credit, the daily press attributes a statement to that effect and that the proposed plant would be capitalized at a million and a half dollars and that it would take upwards of two years to complete the structure.

An invitation has been extended the Canadian Chamber of Commerce in London, to assist toward a Canadian section at next year's British Industries Fair. This fair is conducted on a very large scale and is attended by buyers from all parts of the world. The invitation to the Canadian Chamber is another step in the promotion of the inter-Imperial trade.

Sudbury, Ont.—A. F. A. Coyne, geologist, announced at a meeting of the Board of Trade on August 21st that, after making a survey of over one hundred square miles in the Chelmsford and Larchwood area, he and his associates had come to the conclusion that there was anthracite coal in the Sudbury district, and that same was present in commercial quantities. Mr. Coyne's associates were two mining experts from the Scottish coal fields. Samples of the purest form of anthracite coal were produced to support their statements. On some farms coal was discovered at a depth of 18 inches. Mining operations in a small way were started near the C.P.R. station at Chelmsford.

Montreal.—The Quebec provincial representative in London, England, states that at present there exist discriminatory freight rates, and that the existence of these has prevented a Quebec firm in the asbestos business from securing a large order. The firm forwarded a complaint to Col. Pelletier, Quebec's agent-general, who investigated the condition and reported that asbestos can be brought from South Africa to England for $12.00 a ton, while the rate from Canada is $17.00 a ton. At the same time, Canadian asbestos can be shipped to Cherbourg or Havre for $13.00 a ton. Local interests intend to seek an explanation.

Belleville.—The Hydro-Electric Power Commission on August 22 officially fed into the system a new block of 4,000 h. p. which was developed by one of the two new units at the Ranney falls development of the Trent valley system. The second unit will be in operation within ten days. At that time there will be 10,000 h. p. developed at Ranney falls, which is considered to be its capacity. Construction work has been under way for over eighteen months, and it is stated that the cost has been in excess of $1,000,000. The plant is situated about two miles from Campbellford, Ont. The head of water in summer is 46 feet and in winter this is increased to about 53 feet, as certain lakes can be lowered when navigation closes on the Trent Canal. It is figured that with this additional power available the district will not suffer from a power shortage such as existed during the past summer.

Canadian purchasing agents will hold their annual convention in Montreal, Oct 7.

H. S. Cook & Co., have leased the foundry and stove department of the New Burrell-Johnson Iron Co., at Yarmouth, N. S., and will conduct a general foundry business.

Discussing the future of the National Exhibition, Toronto, John G. Kent, managing director, predicts that the time will come when every nation in the world will have a representative building there.

Peckovers, Limited, Toronto, have been appointed distributors for Ontario of Monel Metal products by the International Nickel Co. The material comes in bars, sheets and plates, and shot for foundries.

Trenton's new industry, the Dominion Combing Mills, Limited, will mark a forward step in the Canadian Woollen industry. The corner stone of the new million-dollar mill was recently laid by E. Guss Porter, M. P. for West Hastings.

On investigating the death of a workman at the plant of the British-American Oil Company, Toronto, a coroner's jury recommended "to prevent the recurrence of such accidents, that the company adopt some mechanical contrivance, such as a suction draft to draw off all gases which might form in the combustion chamber of the oil still."

McGregor and McIntyre, of Toronto, have obtained the contract for the sheet metal and steel for the $600,000 collegiate and vocational school building to be erected by the school board of St. Catharines, Ont. This firm has likewise been awarded the contract to supply the structural steel for the Gledhill school in Toronto.

It is stated that the number of men employed in the steel plants of Sydney is less than those in the swordfisheries of Cape Breton. According to a despatch from Halifax, the fish are caught, cleaned, iced, boxed and shipped in a special fleet of refrigerator cars by the most direct route to Boston. The catches are enormous and there is a steady market found at 13 cents a pound on board ship.

An example of the superiority of electric power over steam is to be found in the rock-crushing plant at Hagersville, which, among many other things, supplies the M. C. R. with ballast material, says a St. Thomas report. For some time it has been impossible to make the steam-operated shovel keep up with the crushing equipment, which was electrically-driven. A few days ago one of the electric shovels used on the Chippawa Canal excavation was secured from the Hydro Commission and now this shovel only operates a small part of the time to maintain the supply for the crusher.

Hugo A. Gutenkunst, founder of the Canadian Malleable Iron plant, Owen Sound, is at present connected with the Milwaukee Malleable & Grey Iron Co. and the Milwaukee Hay Tool Co. While on a recent visit to Owen Sound, he said that business conditions in the States are rapidly improving, and with the settlement of rail and coal strikes he predicts a period of splendid business.

The Hamilton Gear Co., Van Horne St., Toronto, are at the present time making a large number of gears for rubber machinery. This firm has completed quite a number of these gears lately and if it were not for the large capacities of their gear cutting equipment, it would be impossible to handle the diameters which are at present coming through the shop. This company have also adopted the three color system on all patterns, as it avoids confusion and is much better for their class of work than the ordinary two-color system. They report business is quite a bit better and look for still further improvement in the near future.

As an indirect result of the coal strike and rail difficulties of the past months, the industrial situation in the States is rapidly assuming an acute condition. The announcement that all of the Ford plant and assembly factories will close about the middle of September, is only the commencement of a general tie-up of large manufacturing plants if the present state of affairs should continue. It is stated that the closing of the Ford plants will directly affect about 75,000 men and that several hundred thousand men in associated industries may be out of work owing to the suspension of automobile activities.

The Harmer-Knowles Motor Truck Co., Van Horne St., Toronto, are going to show a truck exhibit in the Arena Building at the Toronto Exhibition. They will display trucks from one ton capacity up to three and a half tons, and on all trucks from one and a half tons upwards, the Hamilton Reduction Axle will be used. In addition to the complete truck which will be shown, they are going to display a complete axle assembled, but mounted without the housing so that the construction can be plainly seen. The Hamilton Gear Co., Van Horne St., Toronto, who are the manufacturers and designers of this Hamilton Double Reduction Axle, make certain claims for the construction, which are as follows:— They claim that the construction and double reduction feature eliminates sliding motion, and that the patented brake design which they have has about five times the braking effect of the usual brakes, and over twice the effect of any other. They also claim several safety advantages for this class of brake, and are willing to show the features in detail to those interested. The braking surface is exceptionally large in diameter, and the construction of shoes is exceptionally rigid and has a floating effect, which helps considerably.

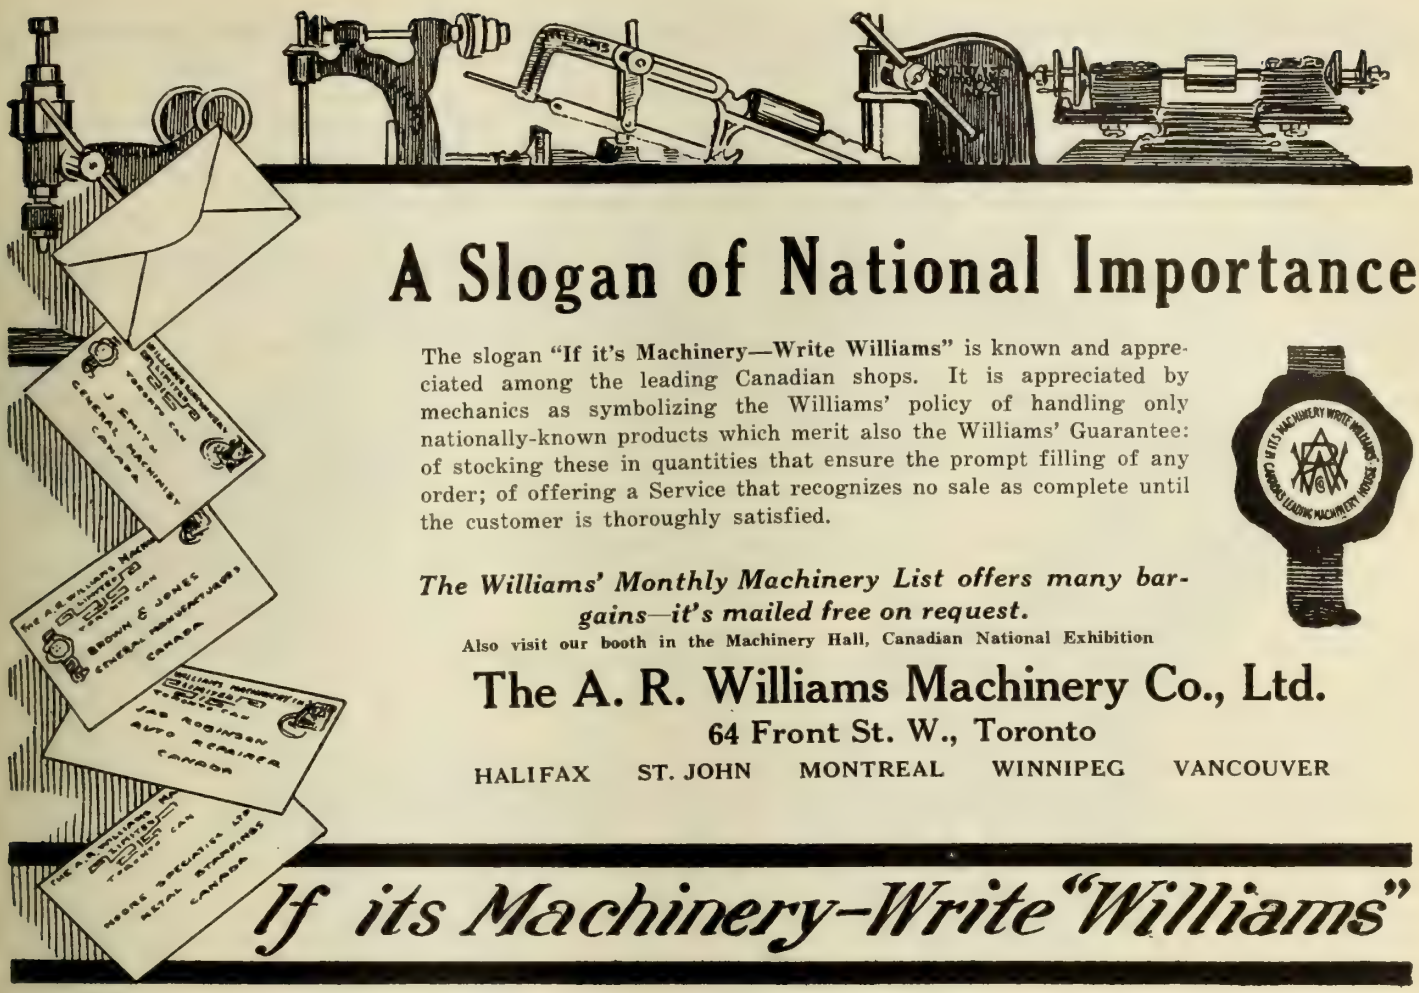
Montreal.—Roland Yeates of the Yeates Machinery and Supply Co., and Russell Wilson, for nine years with Legare Automobile & Supply Co., have been appointed exclusive agents in Montreal and vicinity for the Franklin Automobile Co., of Syracuse, N. Y. Mr. Yeates and Mr. Wilson have opened their show rooms in the new Birks building in Cathcart St., under the firm name of Franklin Montreal Motors, Ltd. The service station will be located at 767 St. James St., where H. D. Hekkema will supervise a staff of factory trained mechanics who are familiar with all the details of the Franklin car.

In the merger of the Bethlehem-Lackawanna steel interests, details of which have just been announced, there will be a readjustment of stock holdings whereby the Bethlehem and the Lackawanna combined will have $77,000,000 in preferred stock, and $82,608,500 common. Among the projected plans for enlargement growing out of the putative increases in business, the directors say that from $10,000,000 to $15,000,000 will be spent in improving and enlarging the Buffalo plant of the Lackawanna.

Montreal.—It is being intimated that the Dominion Glass Company, Limited, will shortly undertake the construction of a large, modern glass plant in the vicinity of Montreal. At the present time the company is operating two smaller plants here, one being located at Point St. Charles and the other on Delorimier Avenue in the east end. These plants have about reached the limit of their efficient expansion. The proposal is, it is understood, to erect one large plant here which will not only look after the business now being handled by these two plants, but will also provide for any expansion in the company's business which can be foreseen at present.

Ottawa, Ont.—After long drawn out negotiations the Hull Electric Co. has acquired certain holdings in Low Township on the shores of the Gatineau river. The title includes the riparian rights to the Paugun falls, which falls are situated about thirty-five miles from the city. In the course of the next year it is planned to establish a hydro-power plant which will have an ultimate capacity of 150,000 h.p. The preliminary estimates of the total cost of construction are said to be about $10,000,000.

It is stated that it will take two years to complete the work. It will be necessary to construct a large viaduct and dam, which will require about one thousand workmen. As far as possible the local men will be employed. Work will be commenced before the early summer of 1923. At the present time the total power generated by the hydro plants at Chaudiere falls on the Ottawa river between Ottawa and Hull is slightly less than 50,000 h.p. Thus it is expected that the new plant with its large additional power will be the means of attracting industrial establishments to the district.



A Slogan of National Importance
The slogan "If it's Machinery—Write Williams" is known and appreciated among the leading Canadian shops. It is appreciated by mechanics as symbolizing the Williams' policy of handling only nationally-known products which merit also the Williams' Guarantee: of stocking these in quantities that ensure the prompt filling of any order; of offering a Service that recognizes no sale as complete until the customer is thoroughly satisfied.
The Williams' Monthly Machinery List offers many bargains—it's mailed free on request.

If its Machinery-Write "Williams"

Montreal.—Frank Scott, vice-president and treasurer of the Grand Trunk Railway System, resigned on Aug. 25th after a continuous connection with the company for forty-four years. The resignation was accepted at a meeting of the board of directors, and will become effective on September 1st. James A. Yates, who has been Mr. Scott's assistant for many years, was appointed to the post vacated by Mr. Scott.

Montreal.—The Quebec division of the Canadian Manufacturers' Association has notified all members to file at headquarters a specification of their coal requirements for the balance of the year. The association has secured a small quantity of Canadian, Welsh and English coal already, and anticipates increasing this supply. The association distinctly states that it is not interested in anthracite coal, or any other fuel that is required for domestic purposes. It is understood that as soon as the requirements of the members are known that active steps to procure the coal will be taken.

Montreal.—An order for 150 street cars which was placed recently with the Canadian Car & Foundry Company, Montreal, by the Toronto Transportation Commission, is being handled by the company's Montreal plants. There is also a certain amount of repair work passing through the plants of the company as well as other equipment companies in Canada. The Grand Trunk Railway is having 100 refrigerator cars repaired by the National Steel Car, and 500 coal cars and 500 box cars repaired by the Canadian Car & Foundry and Eastern Car. The Canadian Pacific Railway has ordered 250 refrigerator cars from the National Steel Car. It is also reported that the Canadian equipment companies are also in line to receive some very fine business from the United States, owing to the strike situation there. This will be in the nature of repair business to locomotives and cars, and barring an early settlement of the strikes this business may run into large figures.

BOOM IN WELSH COAL INDUSTRY

According to a trade commission report from Bristol, Eng., the present American demand for Welsh coal has been a great thing for the industry, which was in a dead slump. It has increased its proceeds, improved wage positions, and the capacity of the industry to give more employment. The report continues: "The American demand is essentially of a temporary character. No one is in a position to say how long or how short the duration of it will be. In fact, it may have ceased before this report is printed. The boom came without any intimation; it may disappear practically without any warning. The demand for British coals will cease immediately the emergency which has created it disappears. Already soaring prices have affected orders, and there has been a big rise in shipping freights; practically all the free coal has been bought, and salesmen are holding off the market for the present. In fact soaring prices and the inability to deliver, are beginning to lessen the new orders. The boom came at a most providential time as conditions in the trade were very unsatisfactory. Steps were being taken to close down some of the older pits, and as far as possible the men displaced were being put on double shifts at the other colleries, enabling outputs to be maintained and lowering the cost of production. Indeed Welsh colliery owners have been going through, until the present boom, a bad time, having to compete very keenly with the north country, and the special steps that had been taken to uphold Welsh prices had to be abandoned quite recently when it was found that orders were being lost. Thus the American demand has been most opportune for the South Wales coal miners' area."

Do what you have to do so well that the boss won't have to do it over again.

FAVORABLE REPORT FROM CITY OF CALGARY

Discussing the western outlook, John Wilson, assistant secretary of Calgary Board of Trade, writes Canadian Machinery as follows: "It may be of interest to your readers to learn that as a city of home owners we are second out of twelve of the largest cities in the Dominion.

"With the prospect of a good crop throughout the southern area, business conditions are particularly favorable, and compare very well with those of a year ago. The coal strike and the effort to create a Wheat Board has had some effect, but we hope that with the air clearing in both these matters, that we shall again resume business on a sound and good basis.

"Like all other cities in the Dominion the unemployment problem is one that is engaging our very serious attention, and, while we look with optimism to the future, we feel very keenly that this problem is one that has to be handled firmly and intelligently. We do not hope that the same conditions that prevailed regarding the unemployed in our city last year will again obtain this winter, and are already devoting considerable time with a view to eliminating as far as possible the difficulties that presented themselves last season.

"No new industries are at present in prospect, but many inquiries have been made during the past year regarding the possibilities of industries locating in our city."

INDUSTRY IMPROVES IN SHERBROOKE, QUE.

Sherbrooke, Que. — Canadian Brakeshoe Company Limited recently associated with the Holden interests, has acquired, it is reliably reported, a large piece of land on Belvidere street, familiarly known as the old cemetery property, at $30,000. The acquisition of this property is held to be the forerunner of extensive developments to be undertaken by the Brakeshoe people, and is looked upon very favorably in industrial circles.

Contrary to the general impression that the summer season is dull and stagnant from an industrial point of view, states the report, a brief survey of conditions as they apply in the Sherbrooke industrial world shows that a steady improvement is being shown all along the line.

The Canadian Ingersoll Rand Company finds itself in a better position than it has been for many a month. The MacKinnon Steel Company reports conditions to be very favorable, with prospects bright. The Beckwith Tool Box Co. Ltd., is very satisfied with the recent trend of business, and a gradual improvement is evident.

The E. and T. Fairbanks Co. had a splendid month in June and while the early part of July dropped off a little, better prospects are in sight and the present situation is quite favorable. The Whiting-Davies Company has been fairly rushed with business of late, and conditions are much improved over last year.

The Julius Kayser Company observes that while the fall business has been decidedly poor, practically negligable, the spring business is exceptionally bright, and orders for next January are better than those of last year. The company intends closing the entire plant for a period of three weeks. This will enable the company to make a complete inventory, while the machinery will be completely overhauled. The plant will reopen at full blast on September first.

The general feeling appears to be that industrial conditions are showing a great improvement over last year, but that better business can only come gradually, without any overwhelming rush. In practically every instance an improvement is noticed and prospects are decidedly encouraging.

BIG SUM FOR MONTREAL HARBOR

Montreal.—Following the visit of the Hon. Ernest Lapointe, Minister of Marine and Fisheries, to the port of Montreal on August 18, it was officially announced that plans for the improvement of the Harbor, which involved an expenditure of $4,000,000 had been sanctioned. These plans embrace the construction of a new elevator at Tarte Pier, which will have an initial capacity of 2,000,000 bushels of grain. It will be ultimately increased to 8,000,000 bushels. The preparations of the designs for the new bridge across the river, the extension of high quay walls between sections 25 and 35, the extension of the wharf at the Imperial Oil Company's plant by 500 feet, the extension of Jacques Cartier, Alexandra, and King Edward piers, the improvement of the channel approach to Bickerdike pier, and the paving and extension of the Harbor Railway terminals to the new wharf levels east of section 25, were the other improvements that were sanctioned. Work on the various projects will be commenced immediately. The first unit of the new elevator will be completed by the autumn of 1923. The new elevator will be able to receive grain from lake vessels at a rate of 40,000 bushels per hour, and in the same time will be able to unload 24 cars or 48,000 bushels, the cars being emptied by car dumpers four at a time. The elevator will be able to ship grain to ocean vessels at the rate of 90,000 bushels an hour. Shipping can be done at seven berths, each of which will be provided with two conveyor belts.

Montreal.—Official announcement was made at the head offices of the Canadian Pacific Railway on Aug. 25th of the promotion of two of the company's higher passenger officials. C. E. Ussher is made general passenger traffic manager, and C. B. Foster who has been assistant passenger traffic manager of Eastern lines, becomes passenger traffic manager of all rail lines.

TO DEPICT SAFETY WORK

Ontario Safety League announces that through the courtesy of John G. Kent, managing director of the Canadian National Exhibition, they have been granted 1,200 square feet in the west annex of the new Arena Building, for a safety exhibit during this year's fair.

Individual, public and industrial safety exhibits will be shown with some striking examples of automobile wrecks, depicting the fatal results of carelessness in connection with traffic. H. H. Couzens, of the Toronto Transportation Commission, has had built especially for this exhibit, a section of a passenger car, to enable the Ontario Safety League to demonstrate, as far as possible, safety in connection with street car traffic.

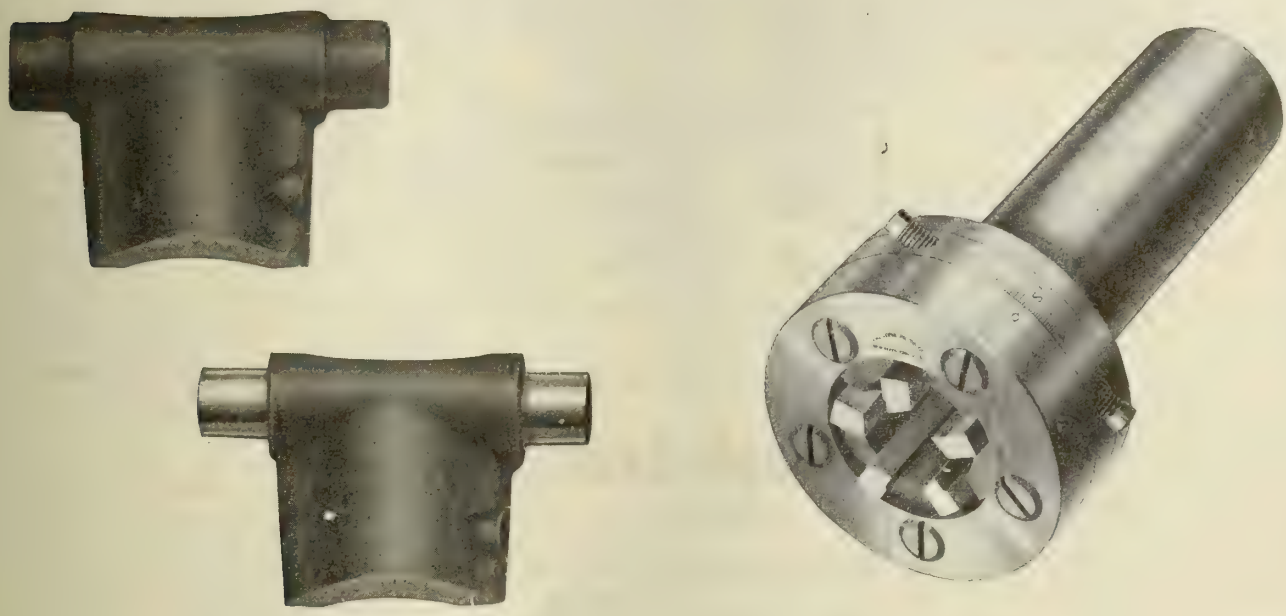
The Assistant District Commissioner of the Boy Scouts, M. E. O'Callaghan, will very kindly have some of his Boy Scouts give, two or three times a day, an exhibition of resuscitation from drowning. This, in itself, is a matter with which we should all be familiar, as fatalities from the water hazard alone costs us each year, in Ontario, some 365 lives.

IMPROVED CHAIN PUMP

No form of engineering is more ancient and at the same time more fascinating than that connected with the raising of water. Primitive races had various ingenious ways of carrying out the operation, and some of our modern methods are in a direct line of evolution from appliances used many centuries ago. One of the most remarkable kinds of pump takes the form of an endless chain, the lower part of which dips into the water to be raised. When the chain moves at high speed the water gets caught up and carried to the top of the driving pulley. Primitive and inefficient as this method may seem, it is extremely convenient for many purposes and can be developed to give most satisfactory results. One of the latest firms uses a very special chain, carrying at right angles to its length spiral coils of steel wire which fit into each other in a most ingenious way. This arrangement enables an exceptionally large volume of water to be caught up. During a recent test made in London a chain of this kind running at a speed of 840 feet per minute, raised 300 gallons per minute to a height of over 80 feet. The pump was driven by an electric motor of about 14 horse power. The largest lift possible in one stage with this pump is about 350 feet. One advantage of the pump is the ease and rapidity with which it can be installed. In one case the whole outfit was set up and started within five hours from the time that the various parts were delivered on the site. Not only water but oils, liquid manure and indeed practically any kind of semi-liquid can be raised with the chain pump, which, by the way, is easily operated by unskilled labor.

2,000 A DAY

$\frac{1}{16}$" TURNED DOWN ON 2,000 DROP FORGINGS WITH A GEOMETRIC ADJUSTABLE HOLLOW MILLING TOOL



There is an extensive quantity of milling that is done with great economy by the use of GEOMETRIC ADJUSTABLE HOLLOW MILLING TOOLS.

Like all other Geometric Tools the Hollow Mill is regarded as superior at home and abroad. A Sydney (New South Wales) man volunteers the good information that he has used different styles of GEOMETRIC DIE HEADS and GEOMETRIC HOLLOW MILLS quite a lot, and after cutting threads under all sorts of conditions with all sorts of methods on his side of the world and in England, he has arrived at the conclusion that the GEOMETRIC WAY CANNOT BE EQUALLED.

The Geometric Hollow Mills provide an efficient and economical method of reducing duplicate parts to an exact diameter prior to threading and for brass finishing.

Send for the Geometric Adjustable Hollow Milling Tool Booklet if you are interested, for it tells what these tools are doing.

Greases will practically always show some acidity on test, but unless moisture enters the bearing, no corrosion will occur even though the acidity be as high as 5 per cent. The acidity of such acids as these is very slight as compared with the action of the mineral acids.

The fatty acids contained in animal and vegetable oils are comparatively inactive with respect to metals and when the oil contains no moisture are perfectly harmless so far as their effect on metals is concerned. They do, however, cause emulsions, sludges and deposits, when mixed with water and subjected to heat.

ONE DEATH EVERY SIX MINUTES

Detroit, Mich.—Seventy-six thousand accidental deaths—a life needlessly snuffed out every six minutes—is the astounding bill charged against careless America during 1920, according to the report of the public accident statistics committee of the National Safety Council presented at the eleventh annual Safety Congress which opened here recently.

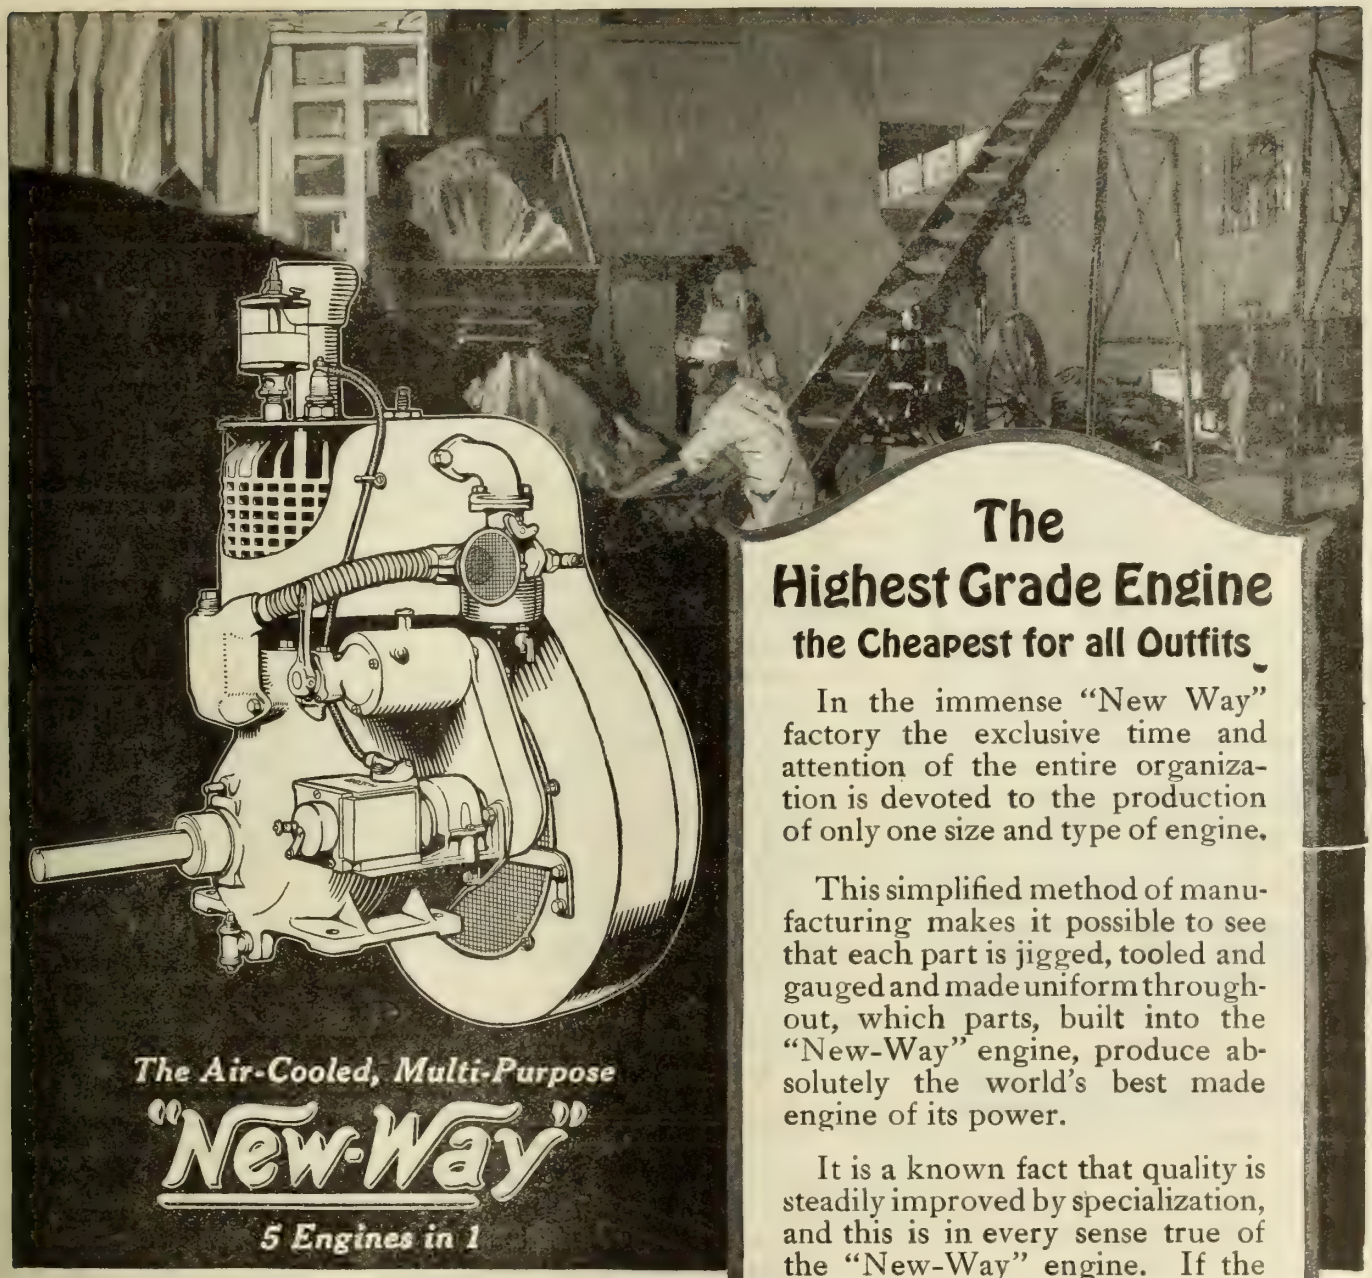
While the 1920 toll from all public and industrial accidents—representing the total population of the state of Nevada—is a decrease of 3,300 over 1911, the beginning of the decade, there is only a balance of 400 on the credit side of the ledger over the 1919 total. This record is viewed with concern by the nation's leaders of organized accident prevention since the yearly downward tendency of accidental deaths in the United States during the past decade, constant up to 1919, came to a halt in 1920.

Automobile accidents are held to be in part responsible for the unfavorable experience of 1920; in that year there were 1,200 more deaths from that cause than in 1919. The chief reason for this, it is pointed out, was the large increase in the number of automobile users. The automobile fatality frequency for 1920 was 30 deaths a day, a total for the year of 11,000. The 1921 estimate of auto deaths, based on figures now available from 50 of the largest cities, indicates a considerable increase over 1920. General traffic accidents in 1921, however, will show a 5 per cent. decrease over 1920, it is believed.

Over twice as many men died accidentally in 1920 as did women, the figures showing in round numbers 55,000 male fatalities as compared with 21,000 women. The latter, however, suffered greatly from domestic hazards, 6,000 having died from falls and 4,800 from burns; 2,756 died from injuries received in automobile accidents. Auto accidents were responsible for 8,300 deaths among men, while railroad mishaps caused 6,930 fatalities.

In commenting on the serious aspect of this continued life wastage through suppressible hazards, the report points out that had the American nation exercised the same regard for the life of the citizenry evidenced in England and Wales in 1920, there would have been 37,000 fewer lives lost in the United States. The death rate in England from 1911 to 1920 was 369 accidental fatalities for each million of population; in the United States the rate for the same period was 714, an uncontrovertible indictment in cold numbers of a national conscience which annually permits the killing and maiming of thousands through preventable accidents.

The reports adds: "The American population is sadly in need of a conscience with respect to accident prevention."



The Air-Cooled, Multi-Purpose

"New-Way"

5 Engines in 1

These Twelve Superior Qualities Should Convince Anyone

1. Air Cooled. No freezing—no boiling—nooverheating—nowatertroubles.

2. Fuel. Operates as successfully on kerosene as gasoline. Select only this type engine.

3. Ignition. Bosch Magneto only—insures ignition reliability. No cheap battery or unreliable magneto used.

4. Power. Variable from 2 to 5 H. P. Controlled by automatic throttling governor. This engine meets eighty per cent of the stationary engine power requirements.

5. Weight. Delivers more horsepower per pound for its operating weight than any other complete engine.

6. Carburetor. Equipped only with float-feed automobile type instead of common mixing valve — insures easy starting, high economy and smooth operation.

7. Lubrication. Dustproof. All wearing parts are enclosed and run in a bath of oil—insures long life.

8. Balance. Mechanically and accurately balanced to eliminate vibration—makes use ideal on light portable machinery.

9. Compactness. Complete in one unit. Can be mounted in small space. With or without sub-base.

10. Dependability. Building one standardized engine only means uniform quality and superior service.

11. Dynamometer Test. Only stationary gas engine we know of using this exacting test.

12. Performance and Satisfaction. Everywhere, manufacturers and dealers of the highest class are standardizing on the "New-Way" on account of its superior merits and past performance.

The Highest Grade Engine the Cheapest for all Outfits

In the immense "New Way" factory the exclusive time and attention of the entire organization is devoted to the production of only one size and type of engine.

This simplified method of manufacturing makes it possible to see that each part is jigged, tooled and gauged and made uniform throughout, which parts, built into the "New-Way" engine, produce absolutely the world's best made engine of its power.

It is a known fact that quality is steadily improved by specialization, and this is in every sense true of the "New-Way" engine. If the "New-Way" experts spent their time over a multitude of sizes and outfits, the highest quality could not be obtained at such a low cost.

With the "New-Way" engine on your outfit you will obtain the maximum dependable service with the least expense. This means practically no idle men waiting for an engine to go. The "New-Way" always "Goes and Goes Right."

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

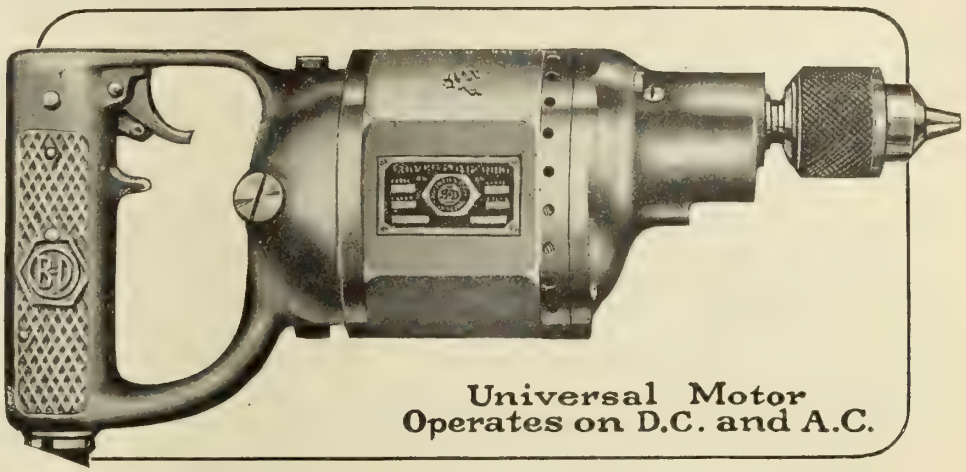
BLACK & DECKER QUARTER-INCH DRILL

"With the Pistol Grip and Trigger Switch"

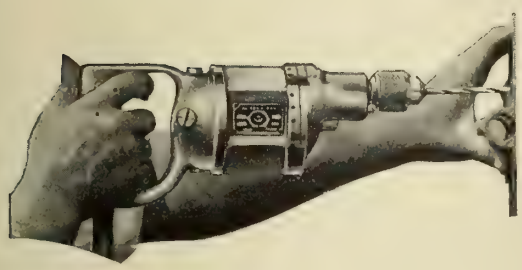
$49.00

Weight 5 lbs.

1922 Model
1922 Price



Universal Motor
Operates on D.C. and A.C.



Standard Black and Decker Portable Electric Drill, *"With the Pistol Grip and Trigger Switch."*

In design and construction the same as the larger sizes. Powerful, durable, comfortable to handle and perfectly controlled. Nothing in the way of ability or durability has been sacrificed to obtain this light weight. Particularly adapted for close corner drilling.

Very accessible. All bearings removable and renewable. By removing four screws, complete switch mechanism, motor commutator, field leads and cable terminals may be uncovered. Armature bearing is carried in a spider integral with motor case, consequently drill may be inspected or commutator cleaned while machine is running.

Brushes may be quickly and easily renewed from outside of motor case. Flexible cable is attached to screw terminals on the switch block so that cable may be renewed when necessary quickly and easily without soldering any joints.

SPECIFICATIONS

HOUSING—Aluminum alloy (No sheet metal is used)

MOTOR—Constructed and insulated the same as the larger Black & Decker Drills. Universal. Operates on direct or alternating current.

AIR COOLED—

GEARING—Double reduction stub tooth gears, cut from chrome nickel steel, heat treated (The toughest, longest wearing gears engineers have been able to design.)

NOTE—No brass gears are used in any Black & Decker tools.

CONTROL—*"The Pistol Grip and Trigger Switch."*

CHUCK—Three jaw chuck for straight shank drill bits up to ¼ inch.

FLEXIBLE CORD—Special light weight rubber covered duplex electric cable, fitted with separable attachment plug.

NO LOAD SPEED—1600 R. P. M.

NET WEIGHT—5 pounds.

The fact that Canadian Industrials insist upon the finest tools and equipment obtainable makes BLACK & DECKER a natural choice.

MADE IN CANADA

A very substantial reduction in prices has been made possible by the establishment of our Canadian factory.

CREDIT

BLACK & DECKER National Credit Service enables any reliable person in Canada to purchase Black & Decker equipment from his jobber on terms that permit the equipment to pay for itself.

Miniature catalogue will be supplied on request.

To Holders of Five Year 5½ per cent. Canada's Victory Bonds

Issued in 1917 and Maturing 1st December, 1922

CONVERSION PROPOSALS

THE MINISTER OF FINANCE offers to holders of these bonds who desire to continue their investment in Dominion of Canada securities the privilege of exchanging the maturing bonds for new bonds bearing 5½ per cent. interest, payable half yearly, of either of the following classes:—

(a) Five year bonds, dated 1st November, 1922, to mature 1st November, 1927.

(b) Ten year bonds, dated 1st November, 1922, to mature 1st November, 1932.

While the maturing bonds will carry interest to 1st December, 1922, the new bonds will commence to earn interest from 1st November, 1922, GIVING A BONUS OF A FULL MONTH'S INTEREST TO THOSE AVAILING THEMSELVES OF THE CONVERSION PRIVILEGE.

This offer is made to holders of the maturing bonds and is not open to other investors. The bonds to be issued under this proposal will be substantially of the same character as those which are maturing, except that the exemption from taxation does not apply to the new issue.

Dated at Ottawa, 8th August, 1922.

Holders of the maturing bonds who wish to avail themselves of this conversion privilege should take their bonds AS EARLY AS POSSIBLE, BUT NOT LATER THAN SEPTEMBER 30th, to a Branch of any Chartered Bank in Canada and receive in exchange an official receipt for the bonds surrendered, containing an undertaking to deliver the corresponding bonds of the new issue.

Holders of maturing fully registered bonds, interest payable by cheque from Ottawa, will receive their December 1 interest cheque as usual. Holders of coupon bonds will detach and retain the last unmatured coupon before surrendering the bond itself for conversion purposes.

The surrendered bonds will be forwarded by banks to the Minister of Finance at Ottawa, where they will be exchanged for bonds of the new issue, in fully registered, or coupon registered or coupon bearer form carrying interest payable 1st May and 1st November of each year of the duration of the loan, the first interest payment accruing and payable 1st May, 1923. Bonds of the new issue will be sent to the banks for delivery immediately after the receipt of the surrendered bonds.

The bonds of the maturing issue which are not converted under this proposal will be paid off in cash on the 1st December, 1922.

W. S. FIELDING,
Minister of Finance.

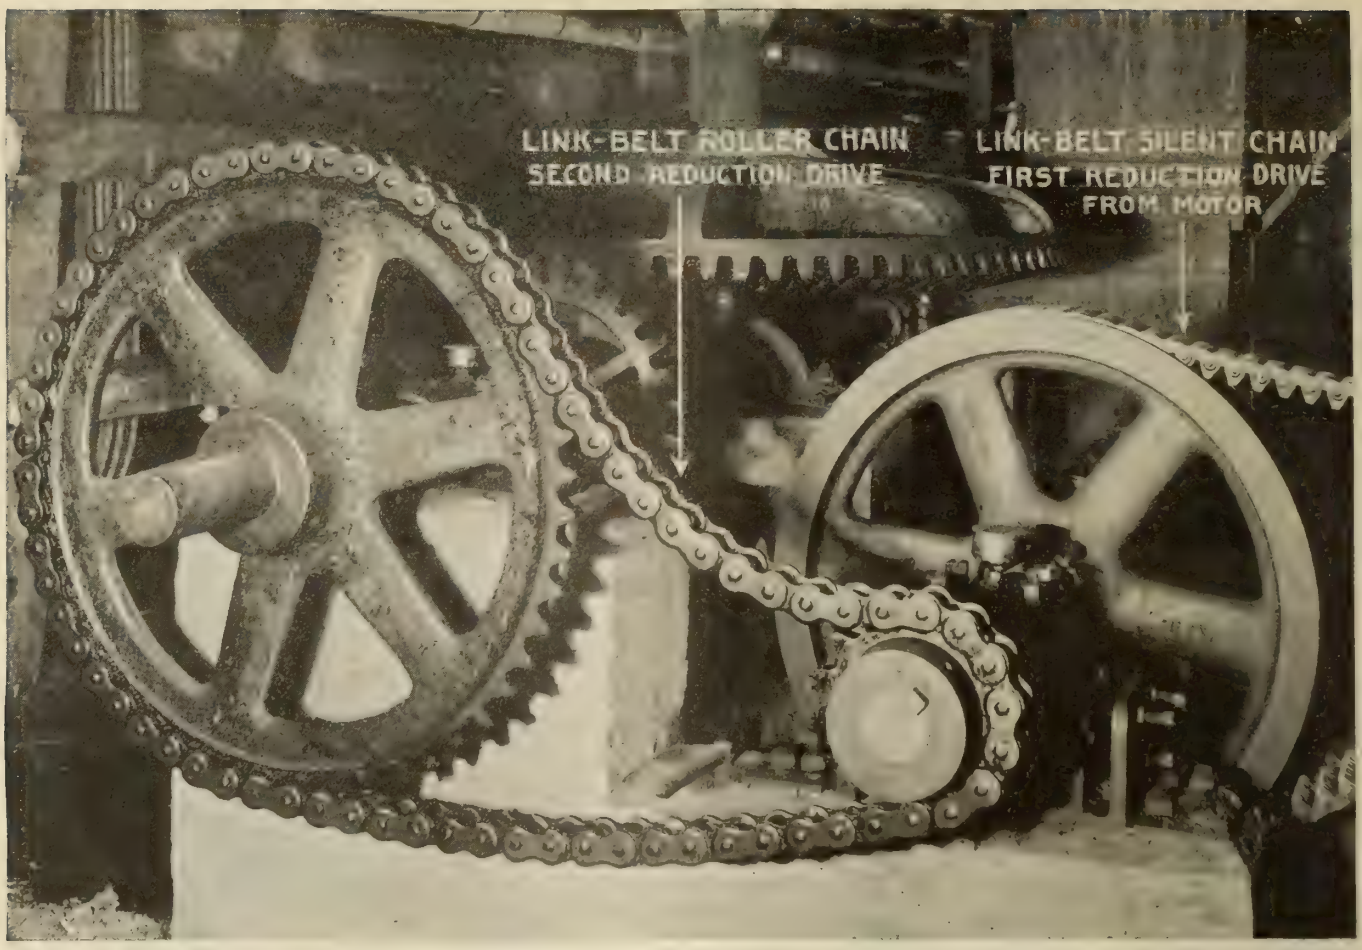
DENNISTEEL

Made in Canada by

The Dennis Wire & Iron Works Co., Limited — London, Canada



BUILDING LONGER LIFE INTO ROLLER CHAIN

Every foot of Link-Belt roller chain is "Proof Tested" for physical strength and wearing value by thorough inspection and tests.

Our data book No. 257 contains much information of interest to roller chain users. Send for a copy. Special corps of engineers at your service.

A DISTINCTIVE feature of Link-Belt roller chain which materially adds to its efficient life, is the famous Link-Belt curled roller.

This roller is made from a special grade, refinement and analysis of steel. Every process in its manufacture develops a fibrous instead of a granular structure, with the grain running around the roller, in a direction which gives the greatest strength and resilience and resistance to shock.

The break in the metal circle eliminates the possibility of internal strains, and presents an opportunity for spring or reaction, cushioning shocks.

This construction is different from that found in any other type or make of roller. Its continued success in service is proof of the superiority of this type of construction.

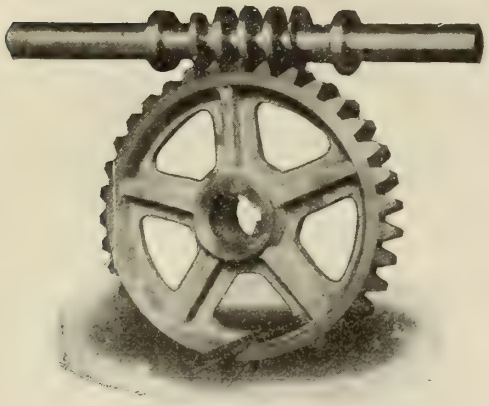
Worms & Gears



Hardened & Ground Steel Worms

Gear Data for your Note Book

Cut this out,—More Coming later

ON GEAR STEELS

from the Hamilton Gear & Machine Co., Toronto:-

The whole tendency of Modern Practice is towards the use of higher grade materials and better workmanship.

Gray cast iron, while the commonest material for gears, is unsuitable for pinions. Use steel. Steel castings make good gears if sound and properly annealed. Steel forgings are superior to castings and are especially favored for pinions.

It is not well to run a gear and pinion both of soft material together on account of wear. Case-hardened and heat-treated steel is the most durable, especially in nickel, chrome or other alloy steels.

For steel castings, use A.S.T.M. specification A-27-21. For forged or rolled carbon steel use S.A.E. specification steel Nos. 1020, 1030 or 1046 straight carbon; Nos. 2315 or 2345 nickel; Nos. 3115, 3215, 3245, 3312 or 3340 chrome nickel and Nos. 6120, 6145 or 6150 chrome vanadium. The last two figures in each indicate the carbon content. We use principally Nos. 1020, 2315, 3245 and 6145.

See our advertisement of July 20th for formula, and Aug. 3rd issue for chart to use in connection with above.

"Belting trouble ends where D.K.McLaren's Belting begins"

The Trademark Is Your Guarantee

Look for the Oakleaf

More Solid Leather to the Foot Than Any Other Belt Made

A sweeping statement—but one which is lived up to in every respect. Every operation in the manufacture of D. K. McLaren's Belting from the vigorous systems of inspection and classification of the hides by experts, to the equally vigorous system of final inspection and testing, bespeaks our right to the claim. No Shoulders, Necks, or Bellies are used in D. K. McLaren's Belting, only the flawless backs of the choicest steers are used.

Every foot of leather in D. K. McLaren's Belting is guaranteed to be

Genuine British Oak Tanned

This should not be confused with the ordinary leather tannage commonly used by belt makers and called "Oak." The Genuine British Oak Tanning is a long-time and expensive process. Years ago it was a closely guarded secret in England; even now, when no longer a secret, it is usually considered "too expensive" to be used generally.

It is this process that imparts to D. K. McLaren's Belting that combination of toughness and pliability which, in turn, gives it a remarkable gripping quality —the chief factor in reducing your transmission costs.

ACME

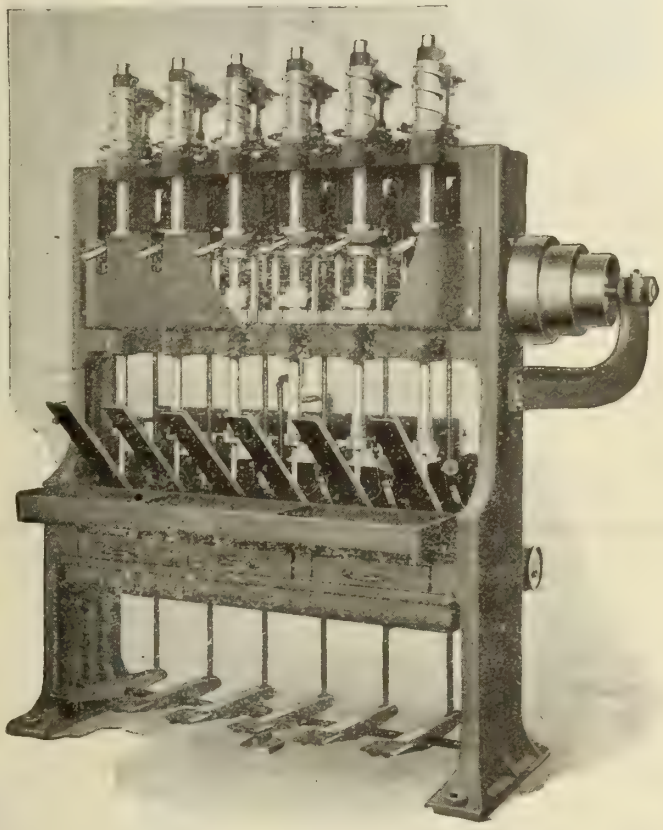
15,000 Threaded Nuts Every Nine Hours

This is the daily output of two "ACME" Tappers which have been running at the same plant for eight years—15,000 5/8 inch threaded nuts per nine-hour day with a spindle speed of 100 r.p.m., the limit of tap endurance on the tough material used.

Speed, however, is not everything. Besides being a high-speed producer, the "ACME" Tapper is capable of precision work under the most severe service.

If you want, then, a convenient tool with a speed limited only by the endurance of the taps; a tool whose accuracy may be depended upon at all times; a tool that will stand up indefinitely; a tool that reflects the long years of building experience—look for the name "ACME".

Our catalogue gives complete details of "ACME" Bolt, Nut, Rivet, Upsetting and Forging Machinery. Shall we send you a copy?



Acme Six-Spindle, Semi-Automatic Nut Tappers have many important features which facilitate operation and increased speed. Each spindle is equipped with automatic lifting device which permits automatic feed to place nut under tap. Every action has been carefully developed and proved correct in practice. Write for further details.

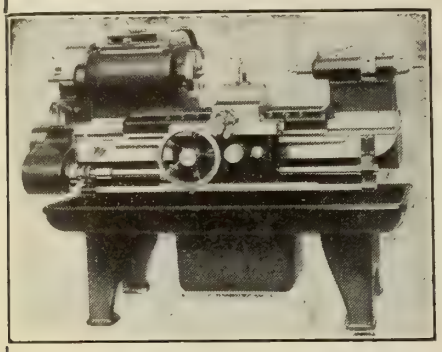
THE JOHNSON FRICTION CLUTCH

AS USED ON THE

"NEW" 12 IN. SUNDSTRAND MANUFACTURING LATHE



Progress in machine tool design demands a reliable and powerful friction clutch. The Johnson Friction Clutch is proving of great value in machine tool designing.

Courtesy : The Rockford Tool Co., Rockford, Ill.

The main drive pulley is mounted on a No. 5 single clutch hub. The same movement that disengages the clutch automatically applies a brake which stops the spindle instantly. The sliding sleeve is machined to act as a brake.

A feature of the Johnson Friction Clutch is the ease of application to particular machine requirements.

Easiest to Install

AN "American" Pulley may be mounted anywhere on your line without stripping or otherwise disturbing the shaft. The "American" Pulley divides; each half is then placed in position and, by a simple tightening of bolts, you secure a steel pulley which grips the shaft so tightly that no amount of reasonable service can loosen it.

A tremendous saving of time and labor.

Write for our book "Getting Maximum Pulley Efficiency". It explains why nearly six million "American" Pulleys are now in operation, here and abroad. Your copy will be mailed at once.

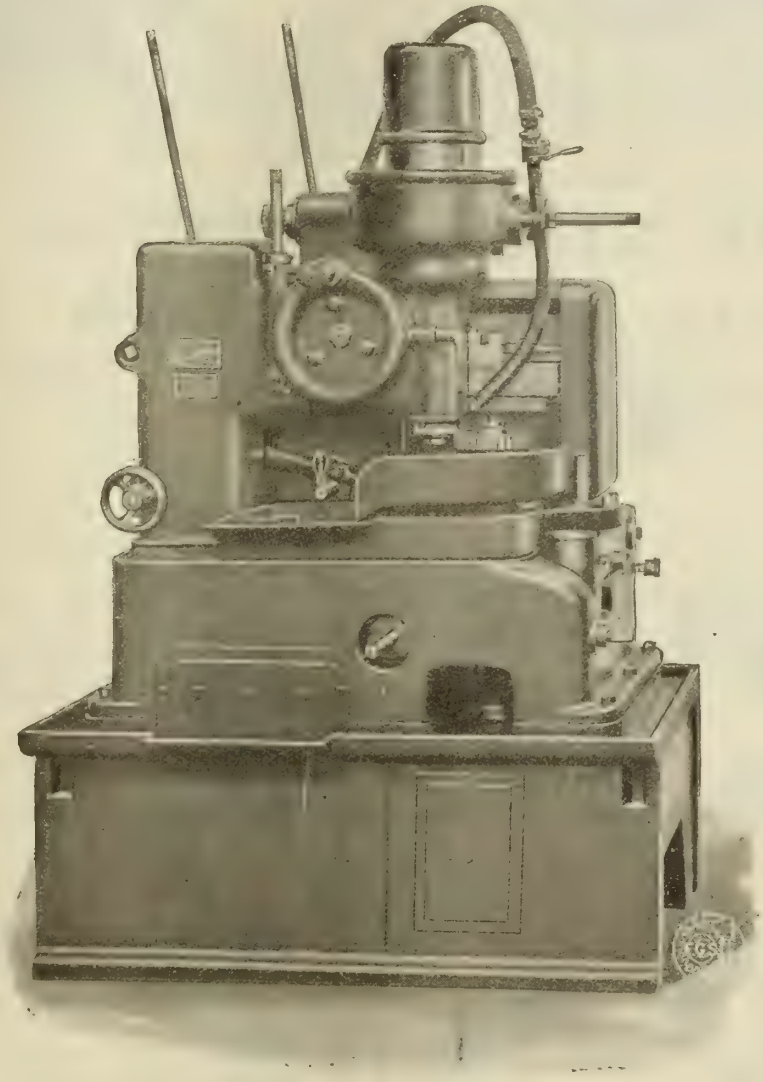
AMERICAN STEEL SPLIT PULLEYS

CUT GEAR COSTS
WITH THE
New Production Gear Shaper



The new production Gear Shaper, illustrated, has been designed to cut gear costs. It incorporates every feature necessary in a gear cutting machine to obtain this result, and still one of the outstanding features of the Gear Shaper principle—accuracy—has been maintained.
It is designed to cut one gear at a time and at a speed which eclipses all other methods.
All operating levers are at the front of the machine, permitting a number to be bolted together and operated as a unit, one 6 H.P. motor furnishing ample power for 10 machines
It incorporates to the fullest extent the three principal requirements of production—high speed, accuracy and simplicity of operation.
See illustrated article in all technical magazines.
Send for our booklet, "A New Development in Gear Cutting," which has been prepared for the benefit of Engineers and Production Managers interested in the best gear cutting equipment available.

Write for your copy now.

Have you any Belt Trouble?

LEVIATHAN AND ANACONDA ELEVATING TRANSMITTING CONVEYING BELTING

THE cause of most belt trouble is not so much inferior quality as the **unsuitability** of the belt in regard to conditions of operation.

Thirty-three years of belt-making have shown us that it is necessary to deal directly with the belt-user that we may apply a belt especially adapted to the conditions to be met.

Following this policy, we have made belting that is giving utmost satisfaction under conditions ranging from zero temperatures to those at which wood will char; where absolute dryness is encountered to those in which both belt and machinery are under water; where the belt runs faster than man has ever travelled to those where the observer can walk as fast as the belt is moving.

Leviathan and Anaconda Belting is a **Canadian Made Product.** Our business in Leviathan is thirty-three years old—**and growing;** not because of the things we say about it, not because it meets certain laboratory specification requirements, but because an increasing number of practical, hard-headed men are proving, **on their pulleys,** that our product is the scientific and satisfactory answer to the belt problems of today.

In what way can we be of use to you?

SPRING NUT

SPRING DIVIDERS #77

The Starrett Spring Dividers No. 77 are made to please the man who is hard to please. They're different from the ordinary dividers. If you will examine the quick adjusting, automatic closing spring nut you can see at once why the 77 appeals to the critical machinist. The thread engages the screw at the slightest pressure when the leg comes in contact with the nut; when pressure is withdrawn, it releases itself immediately, sliding freely on the screw. Its use saves much valuable time in opening and closing. Also made with solid nut.

Why Hendey Shapers Are Preferred

HENDEY

They have, wherever used, brought to light many operations formerly costing more by other methods. They eliminate the expense of building special cutters and jigs for machining small lots of intricate shapes. Their accuracy is unquestionable. Their versatility is an accepted fact.

This Hendey 15-inch Pillar Shaper is freely adjustable while in motion and can be changed at once to any length and position, without stopping.

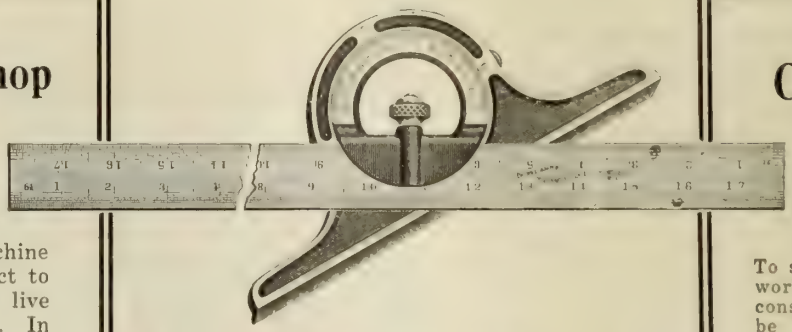
LATHES—MILLERS—SHAPERS AND CENTERING MACHINES

Machine Shop Tools

When in need of machine shop tools, come direct to our store, or, if you live out of town, write us. In either case you are sure of the very best and latest designs, for we carry only the highest grades. Every tool sold is accurate, dependable, and is made from the finest materials.

We carry an exceptionally large range and can give you very prompt delivery. Write us your requirements.



Machine Tools
and Construction Supplies

Having such a complete organization we can supply you with many lines generally overlooked by the ordinary hardware merchant. For example, we can deliver machine tools and construction supplies from stock, thus avoiding unnecessary delay and expense. This is only one phase of our service to the manufacturer, contractor and mechanic.

Construction Tools

To stand up to the exacting work placed upon them, construction tools must be solidly built of correct materials. We pride ourselves that we carry only the very best lines of construction tools and that the maker's guarantee is behind them in each case. We have a reputation second to none in the general hardware and tool business and naturally we intend to uphold our reputation by selling only well-known and proven tools. When in need of any type of construction tool write us. We can quickly handle your requirements.

To Holders of Five Year 5½ per cent. Canada's Victory Bonds

Issued in 1917 and Maturing 1st December, 1922

CONVERSION PROPOSALS

THE MINISTER OF FINANCE offers to holders of these bonds who desire to continue their investment in Dominion of Canada securities the privilege of exchanging the maturing bonds for new bonds bearing 5½ per cent. interest, payable half yearly, of either of the following classes:—

(a) Five year bonds, dated 1st November, 1922, to mature 1st November, 1927.

(b) Ten year bonds, dated 1st November, 1922, to mature 1st November, 1932.

While the maturing bonds will carry interest to 1st December, 1922, the new bonds will commence to earn interest from 1st November, 1922, GIVING A BONUS OF A FULL MONTH'S INTEREST TO THOSE AVAILING THEMSELVES OF THE CONVERSION PRIVILEGE.

This offer is made to holders of the maturing bonds and is not open to other investors. The bonds to be issued under this proposal will be substantially of the same character as those which are maturing, except that the exemption from taxation does not apply to the new issue.

Dated at Ottawa, 8th August, 1922.

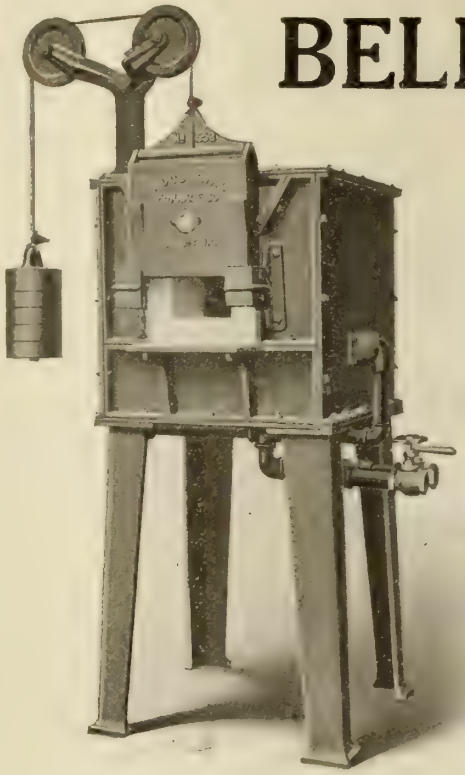
Holders of the maturing bonds who wish to avail themselves of this conversion privilege should take their bonds AS EARLY AS POSSIBLE, BUT NOT LATER THAN SEPTEMBER 30th, to a Branch of any Chartered Bank in Canada and receive in exchange an official receipt for the bonds surrendered, containing an undertaking to deliver the corresponding bonds of the new issue.

Holders of maturing fully registered bonds, interest payable by cheque from Ottawa, will receive their December 1 interest cheque as usual. Holders of coupon bonds will detach and retain the last unmatured coupon before surrendering the bond itself for conversion purposes.

The surrendered bonds will be forwarded by banks to the Minister of Finance at Ottawa, where they will be exchanged for bonds of the new issue, in fully registered, or coupon registered or coupon bearer form carrying interest payable 1st May and 1st November of each year of the duration of the loan, the first interest payment accruing and payable 1st May, 1923. Bonds of the new issue will be sent to the banks for delivery immediately after the receipt of the surrendered bonds.

The bonds of the maturing issue which are not converted under this proposal will be paid off in cash on the 1st December, 1922.

W. S. FIELDING,
Minister of Finance.



BELLEVUE FURNACES

Enable the Operator to Speedily Obtain an Intense, Uniform Heat.

A distinctive feature of Bellevue Furnaces is the accurate way they respond to the will of the operator. They speedily develop an intense heat and are always under accurate control. Bellevue Furnaces are simple and economical to operate. Combustion is perfect and no flames come in contact with material. For oil or gas in seventy-nine different styles or to your order.

Write for our highly illustrated catalog.

Which Factors Influence Your Grinding Wheel Selection?

1. Actual life of grinding wheel measured in hours' service.
2. First cost of wheel.

or

3. Ultimate grinding costs as determined by the wheel, labor, and overhead charges for each piece ground.

Did you ever figure out—

1. How much you lose by using a slow cutting wheel.
2. How much more a glazed wheel is costing you every hour.
3. How much a fast cutting wheel saves you every hour. It may divide your total production costs by two or more.

If the physical properties of the abrasive of which the wheel is made, the grain size in the wheel and the hardness of the wheel, are not all designed for your job—whether it be tool grinding, surface grinding, cylindrical grinding, internal grinding, snagging or any grinding operation—your grinding costs are high.

Norton Alundum and Norton Crystolon wheels are made for all grinding jobs and answer every requirement. They produce at minimum cost.

CANADIAN MACHINERY
AND
MANUFACTURING NEWS

VOL. XXVIII, No. 10 SEPTEMBER 7, 1922

Value of Die Casting to Metal Working Industry

Great Saving in Machining Operations—Product Easily Nickel-Plated—High Rate of Production—All Holes Accurately Cast in the Work—Method of Manufacture

THE die-casting process offers many opportunities for reducing manufacturing costs, when the metals from which die-castings can be made are satisfactory for the parts required. By this process holes, recesses, etc., can be cast directly in the part being made with such accuracy that in most instances subsequent machining is unnecessary. The elimination of machining operations therefore constitutes one of the main savings in the use of die-castings. Even the first cost of the dies is negligible, as compared with the first cost of the machining equipment that would be required for making parts from steel, cast iron, or brass. In any line where die-castings can be used, therefore, their application should be investigated. Many manufacturers of specialties have found that not only is it possible to start a business for the manufacture of a new article with less capital, when the die-casting process is employed (as the dies are cheaper than machine tool equipment), but it is also possible to get under way faster, as dies can be made in a fraction of the time that would be required for fitting up a machine shop.

It has been estimated that dies for making a given part on which a number of machining operations would be required would not cost more than 10 per cent. of the cost for machinery and tools. The manufacturing of the article then reduces itself mainly to an assembling proposition and to the machining and making of such parts as cannot be advantageously die-cast.

Examples of Die Castings

The accompanying illustrations show a number of die-castings that have been produced, and figures indicating the saving resulting from their use will be given. Fig. 1 shows at A a star-shaped faucet handle. This handle costs, as delivered by the die-casting company, including the tapping operation, 65 per cent. of what it cost when made from a brass casting. This includes the cost of dies distributed over a six-month period. The die-cast faucet handles are made from a zinc base alloy, having a tensile strength of 24,000 pounds per square inch. The composition is 88 per cent. zinc, 4 per cent. copper, 6 per cent. tin, and 2 per cent. aluminum. This metal is less expensive than brass, and in addition there is a saving of six machining operations, including a counter-boring operation and two facing operations on each side. To prepare the brass casting for nickel-plating it is also necessary to grind and buff it, while the die-casting needs to be buffed only. The only operations that need to be performed on the die-casting after it comes from the dies are to trim it and to tap the central hole. The counterbores on each end and the surfaces come so accurately from the dies that no further work is required except that of buffing before nickel-plating.

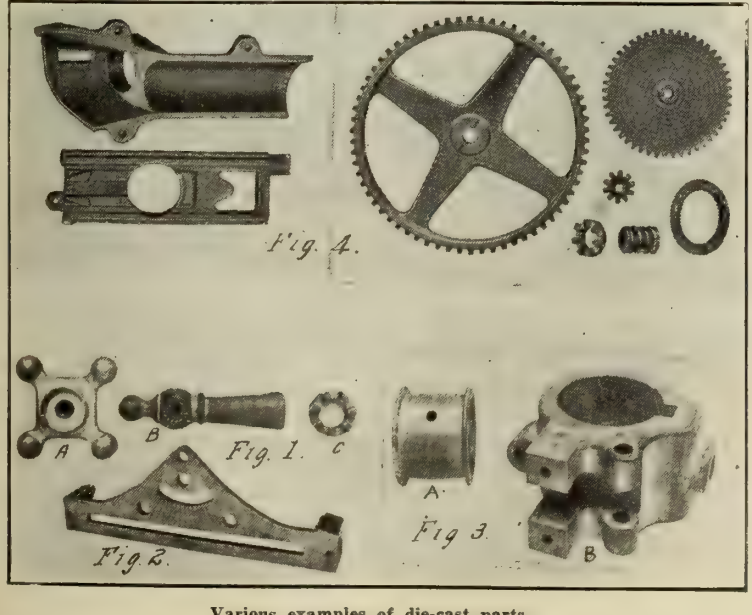
Easily Nickel-Plated

Faucet handles made in this manner have been used for a period of one year and have been found to be fully as satisfactory as brass handles. In fact, they have some advantages over those made from brass. They will take a heavier plate of nickel, and hence will wear longer, and if the nickel-plating wears off, the metal underneath will not show yellow, but the die-cast metal, being in the white metal class, will look more like nickel.

At B in Fig. 1 is shown another faucet handle, delivered at a cost of less than 5 cents, including the cost of the dies distributed over six months' production. No machining work needs to be done on this die-casting whatever. Formerly these handles had to be faced on one side, the center hole drilled and broached, and the hole for the bottom at the end counterbored.

At C is shown a roller bearing cage. In this case the die-casting costs more than the malleable iron casting that was formerly used, as there was no machining required on the malleable iron casting. However, the use of a die-casting meant a saving to the manufacturer of the roller bearings, as the die-cast cages are uniform, while the malleable iron cages are not. Therefore, in assembling the various parts, it was necessary, when using malleable iron cages, to try to fit a number of cages, which was found unsatisfactory for production work. Every one of the die-cast cages will fit, because it is possible to die-cast a part of this de-

Illustrations and information through courtesy of the Superior Die Casting Co., Cleveland, Ohio.



Various examples of die-cast parts.

sign within an accuracy of 0.001 inch. Thus the experience of this roller bearing manufacturer indicates the accuracy of die-castings, and shows that even in cases where the die-castings may cost more than a part made in some other manner, it might, nevertheless, be economical to use them because of other savings resulting from their uniformity and accuracy. The high rate of production obtainable in die-castings, assuring a supply of parts at all times, is also a point to be considered.

Brackets for an X-Ray Apparatus

Fig. 2 shows a die-cast tube stand bracket for an X-ray apparatus. This bracket was formerly made from brass and nickel-plated. When made in this way, the holes had to be drilled and the various flat surfaces milled. The lines shown on the front of the bracket had to be produced by a graduating tool. Now this part is produced by the die-casting process, and no machining is required except the tapping of two of the holes. The large holes in each end of the bracket are in line with each other, and come accurately enough for the apparatus directly from the die-casting machine. All the holes formerly drilled are cast in place. The small holes are accurate within (plus or minus) 0.005 inch, and the rest of the holes within (plus or minus) 0.001 inch. Lengthwise, an accuracy of (plus or minus) 0.001 inch is assured for each two inches, and the width of the long slot is accurate within (plus or minus) 0.001 inch. When zinc base metal is used for die-castings, it is generally possible to obtain a greater degree of accuracy in practically every dimension than can be obtained by ordinary machining methods, when producing work on a general commercial scale in interchangeable manufacture.

The total cost of this piece is less than the manufacturers' former cost of performing only one of the machining operations. In a comparatively small production, the cost of the die would be, say from 20 to 25 cents per piece, but this figure is much less in comparison than the cost of the machine and tool equipment that would be required for machining a brass casting.

Other Parts Produced

At A in Fig. 3 is shown a die-cast pulley, which was formerly made from bar stock. By die-casting, the cost was reduced 20 per cent. The feed-roll clamp B was formerly made from a gray-iron casting and required the boring and reaming of the large hole through it, the broaching of the keyway, the facing on both ends, the milling of the slot between the lugs, the facing of the lugs, the facing of two bosses, and five drilling operations.

These parts are now being die-cast; all holes are cast in place with sufficient accuracy without further machining, and the cost per piece is 55 per cent. of the cost when a gray-iron casting was used, not including the die cost. The latter cost, however, is insignificant as compared with the cost of the machining equipment formerly required, because with a production of less than 2,000 a year, the die was paid for by the first 1,000 pieces through the difference between the cost of die-casting and the machined gray-iron casting. Consequently, after 1,000 pieces had been made, there was a clear saving of 45 per cent. on every piece made thereafter.

Dies in use for two years have produced several hundred thousand castings, and are still in good order. A die for a piece of average design would cost, say $250. If there is a production of 5,000 pieces a year, it will be seen that the die cost per piece distributed over a period of five years would only be 1 cent.

Die Casting Machine

A recent model of die casting machine has a revolving table carrying four dies rotating about a central vertical shaft. The dies may be similar, or different ones may be used in each division, as the operating speed of the machines makes it possible to cast pieces of varying weight at the same time. When operating continuously and four dies in position, eight castings are produced at each complete revolution of the table.

Operating Mechanism

The four dies, which are placed at equi-distant points near the edge of the machine table, are enclosed in die-cages which support the operating mechanism. Through the center of each die-cage is a vertical shaft, enclosed in a sleeve made of steel tubing. The shaft is attached to the upper half of the die, and the tubing is attached to the mechanism that controls the core pins.

To the upper end of the shaft is attached a follower that rides in the upper one of the two grooves in the large cam attached to the main shaft. A follower attached to the sleeve rides in the lower groove. As the table revolves, the shaft and sleeve are raised and lowered by the action of the cams, thus opening and closing the die and setting or withdrawing the upper core pins. The cam grooves are so made that the core pins are placed in position just before the dies are closed, and withdrawn just after the dies are opened.

The core pins on the lower side are held by short levers that ride in curved slots in a round plate resting on the table of the machine and located midway between the four posts that support the die cage. The plate is caused to oscillate as the table revolves, thus operating the core pins as desired.

The Melting Pots

Two metal containers are used on each machine, one on either side of the machine. These boxes are retained by long arms that permit a movement of 30 deg. on either side of a neutral position. The boxes are lined with fire-brick and contain the pot for the molten metal. The fluid metal is forced, by means of a plunger, through a passage to the mouthpiece of the pot into the mold; an automatic stop is provided so that the plunger can only be operated when the nozzle is in correct contact with the die opening. The metal is kept at the proper temperature by means of a gas jet that can be regulated to suit the required conditions. As the revolving table is indexed in casting position, the metal pot moves towards the table and the spout of the pot enters the gate of the die. After the metal is forced in, the metal pot is moved back for the next indexing of the table. Directly after the two dies have received charges of metal they are automatically opened, the core pins are pulled out, the castings are ejected, the dies cleaned and closed, the core pins are pushed in, and the dies are ready for another charge. In the meantime, the other two dies are passing through the same cycle of operations.

As the upper half of the die is raised to the maximum height, carrying the casting with it, a pin knocks the casting loose and causes it to fall onto the plate which can be seen suspended between the upper and lower halves of the dies. The plate is then withdrawn and at the proper time a tripping mechanism causes the plate to turn and dump the casting. After the castings have been removed from the dies, a rotary brush attached to a rack is fed forward across the face of each die, revolving as it goes and cleaning the die. Then the brushes are returned to their places and a powerful jet of air is blown upon the face of each die for the purpose of removing any particles that may have clung to the die.

Cooling System

A complete water circulation system keeps the dies at the proper temperature at all times, the water being introduced through a swivel overhead pipe at the center of the machine, then passing through four radiating pipes that connect with both the upper and lower halves of each set of dies and eventually discharging through the base of the machine.

The pots can be operated by either the plunger method or compressed air, depending upon the kind of metal being used and the preference of the operator. When the compressed air method is used, the air is preheated so that no further expansion will take place when the air comes in contact with the metal. A system of burners surrounding the cylinder keeps the cylinder and piston at the correct temperature, in order to prevent the piston from sticking in the cylinder and to prevent any metal from adhering to the wall of the cylinder.

GOOD INTEREST AND ABSOLUTE SECURITY

A liberal rate of interest with absolute security is the attractive offer made by the Minister of Finance to holders of the Canadian Government war loan bonds maturing December 1, 1922. The offer is not made to investors generally, but only to the holders of the bonds soon to mature. The bonds to be retired, bearing interest at five and one-half per cent., will be exchanged for new bonds bearing the same rate of interest. Further details will be found on page 27 of this issue.

Preparing Molds and Machining Babbitt Bearings

Channel Irons Make Good Ingot Molds—Heavy Bearings Used in Rolling Mill Work—Strong Bracing Required When Pouring Hot Metal—Avoid Damp Molds

By W. S. STANDIFORD

IF IT IS desired to have a supply of babbitt for the stock room, use channel iron as a mold, spacing it off into desired lengths by means of short pieces of boards placed crosswise in the channel. Short sections of suitable sizes as will fit into the melting pot and weighing 50 lbs. apiece, will prove a very desirable weight for stock room shelves. To enable quick repairs to be made in emergency breakdowns of machinery, it is of the utmost importance that a good supply of bearing metal ought always to be kept on hand; as delays will be obviated. The writer has seen cases where much delay has occurred in making repairs through carelessness in keeping track of much-needed supplies by the stock room employees.

Channels For Molds

Channels make very desirable molds for casting bearing metals, as their weight can be controlled by using channels of varying widths. If it is wanted for general use, leave plenty of babbitt in the melting pot until it is needed. While the variety of machines for manufacturing articles are many, the bearings for most of them (outside of roller and ball bearings which are limited in numbers and need not be discussed here) are constructed out of brass, bronze or babbitt; some of the brass and bronze ones being lined with babbitt, those of automobiles are in the latter class. Some factory machines have cast iron shells lined with babbitt. There are two different types of bearing shells used with cast iron retaining walls to give the required strength and rigidity, viz.: Those that are cast in one solid part having no joint, and also others which are made in two-piece sections. The one-piece ones are cast on a much smaller mandrel, each one having a 1/16 inch taper so as to facilitate their removal when the metal is cold.

Machining the Bearing

The babbitt is afterwards bored out on a boring mill to such a diameter as will make a neat sliding fit, all grease slots or oil holes being either cast in or cut when the machining work is done. This style of bearing gives good service on heavy rolling mill or factory pinions. To give an idea of the amount of babbitt required in large pinion bearing retaining shells, it may be stated that some of them need 1,200 lbs. of babbitt. It is customary in doing work with large bearings of the above weight, to cast in the grease slots so as to reduce the amount of work on them to a minimum. Another important factor sometimes overlooked by machinists working on the rebabbitting of large heavy bearings is that they do not use sufficiently strong braces to hold the hot metal in place until it has set. This results in warped castings and also a possibility of the bracing giving away under the pressure of the fluid babbitt and injury to workmen. Care should be taken to place a weight and heavy clamps around the box that is usually surrounded by boards, other clamps holding the mandrel in place. This obviates all danger of a mold bursting.

Air and pouring holes should also be provided so as to obtain sound castings free from blowholes. Taken all in all, the making and handling of babbitt is a very dangerous task; outside of proper securing of molds and mandrels, great care ought to be resorted to so that no dampness or water is in the bottom of shells, while the pouring of hot metal is being done; as it will explode with disastrous results to the workmen around it. The main drawback in casting very large bearings, whether they are one or two-piece ones, exists in the time that is required to cool them so that they will stand handling. This feature can be overcome by having four mandrels of the same size for each set of heavy bearings, and pouring them one after another.

Rounding Corners

If any crankshaft has a rounded fillet, much time and money can be saved by filleting out all mandrels, the latter to contain fillets of the same radius as the crankshaft. Providing fillets on mandrels when the bearing is made not only saves time which is a vital factor in emergency breakdowns, but considerable expense on ordinary occasions by eliminating unnecessary machine work. If a supply of the ready-made finished castings are kept in a stock room, extra rapid work can be done in emergencies, the latter happening in the best regulated factories. In those classes of machinery in which the wear is extra heavy due to a succession of jerks on moving parts, some machinists usually have a narrow brass liner with the same radius of a shaft, cast in with the babbitt, the latter surrounding and holding it in place. This combination enables all such bearings to resist wear at their most vulnerable spots.

The same result can be achieved by adding a much larger percentage of tin and antimony and also some copper to the babbitt; a reduction or an entire elimination of the lead contents tending to give hardness. Increasing the amount of tin and also antimony, increases the cost of bearings, especially large heavy ones. One and two-piece shells usually have their linings held in place (to prevent rotation with their shafts) by means of dovetail grooves or round anchor studs; sometimes both are in use. The extensive employment of large and small electric dynamos and motors in modern rolling mills or other places where the temperature is high, calls for a special grade of babbitt in order to make them give the least amount of trouble, day in and day out. These machines are, as a general rule, in operation continuously for 24 hours; so that their bearings get no chance to cool off. In addition to running in a very hot atmosphere, they also operate in a very dusty one containing very small particles of iron, etc.

Special Composition

For use under such conditions of working, a special babbitt formula is appended, which has been found out by years of experience to give most excellent results.

Special babbitt formula for electric dynamos and motors:

438 lbs. tin
40 lbs. antimony
27 lbs. copper

The above metal is well suited to the high speed and heavy pressures exerted on armature shaft bearings by light and heavy mill motors. As the latter generally have their shafts oiled by revolving rings, the shells of these machines can be made out of cast iron, although bronze may be employed for this purpose if desired. Cast iron ones are the best owing to the rapidity in which they can be relined as contrasted with those of bronze. All motor bearings ought to be poured on a much smaller mandrel, with the latter having a 1/16 inch taper to facilitate ease of withdrawal; they should then be bored out carefully to desired size.

Guard Against Dirt

Extreme care must be taken by the workmen to see that no dirt, dross or iron scale from a very rusty ladle gets into this metal while pouring babbitt into their casing shells, as they will run hot and start to cut the shaft and babbitt lining; the latter melting in spite of the oil rings conveying oil to them. When the babbitt is worn down in shells and has to be replaced with new material, all old metal can be quickly removed by first carefully cleaning them from oil and dirt of all kinds, and then placing them into a pot of melted babbitt; thus melting it out. By adding old metal (providing that it has not been burnt) to the new, expense can be saved in this direction, as such material will be found most useful and again give good service in regard to fine wearing results.

Babbitt for motors and dynamos ought to be kept in a separate place from that used on shafting and other low speed machines, so as to avoid mistakes made by workmen using the wrong metal. Another place where this special motor babbitt can be used to great advantage as regards the quickness in which repairs can be effected on emergency jobs, as well as giving excellent service in regular work, is as a bearing lining for crosshead slides on steam engines, this metal replacing the usual brass ones; the latter requiring a lot of machine work to be done upon them before they are ready for use. As the babbitt ones need less work in that respect, the engine can be gotten into action quicker. The proper lubrication of all bearings of various kinds and classes of machinery does not seem to be as well understood by the average run of factory superintendents as might be the case; many executives think that all that is necessary is to supply machinery with grease or oil and let it go at that, the men accepting all wear on bearings and journals as an evil which cannot be avoided. Guard against this practice. Another factor that has an important bearing upon lubrication difficulties, exists in climatic changes. A grease of sufficient softness that will operate satisfactorily in the summer time will give trouble in the winter, especially when the temperature is down around or below the zero mark. In such cases, it is better to either use a medium thick oil in the winter or an extra thin grease that will not allow the teeth to cut a path through it; oil being preferred.

(To Be Continued)

Grinding is the Best Method of Finishing Hardened Automobile Parts

IN the early period of machine shop development the lathe was the only tool used for producing cylindrical work, but the introduction of hardened steels into mechanisms of every character demanded more efficient methods of coping with changing conditions. The greater degree of accuracy required in precision work necessitated the adoption of grinding machines for finishing work that had been hardened and tempered after being turned. Grinding was first performed by rigging up attachments on the ordinary engine lathe, but the rapid progress of this particular phase of industry soon resulted in special machines devoted exclusively to grinding operations. To-day a wide range of equipment is manufactured, each individual tool designed to take care of a definite class of work.

The development of the grinding machine has enabled manufacturers to reduce considerably the time formerly required for turning work to a definite size. In many plants it is the practice now to rough turn a very large percentage of cylindrical work, leaving the finishing operations to be performed by the grinding machine, which accomplishes the desired results with a higher degree of finish and accuracy.

The operation of grinding is not confined to hardened parts as many pieces are finish-ground direct from the casting or forging. However, it is most essential that grinding be adopted for finishing bearings on shafts that have been heat-treated, and as this process is now recognized as a very necessary part of a great number of mechanical appliances, the possibility of warping and distortion during reheating and cooling, the finishing to size is impractical until after the heat-treating has taken place. Should delicate shafts and irregular pieces be turned to final size and then hardened or heat-treated, the chance of the pieces retaining their shape and accuracy would be very remote, and the process of straightening or aligning would entail a lot of work that would be both tedious and costly. Production would suffer in consequence and efficiency would be brought to a low figure.

An interesting grinding operation is shown in the cut herewith. The view on the left illustrates the steering ball-joints for the Packard twin-six car. The centre view shows the tapered portion being ground on a Norton grinding machine. The abrasive wheel being a 50-M alundum vitrified wheel. The right hand view shows the taper portion held in a collet chuck while the ball end is ground on an automatic radial grinder using a 80-5 Norton elastic alundum wheel.

The other cut illustrates the finish grinding operations on pins and bearings of automobile crankshafts. The grinding machine has made it possible to use special tough alloy steel for crankshafts and camshafts and it would not be economical to finish such shafts in any other way.

Safety in Handling Material Lessens Costs

Proper Training of Workmen Gives Three-fold Profit—Lessens Waste Through Accidents and Compensation Costs, Increases Production—Working With and Not for the Employer—Great Modern Improvement

THIS subject quite naturally recalls to our minds the varied operations which have come under our observation during many years which have now passed into history. We can readily recall how we would pause in our own work and observe the actions of others, they being either so-called "unskilled labor" or mechanics of some special class. While watching the various operations, no doubt, there was a question in our minds—why is the work being done in that manner and not in some other? The past twenty-five years have witnessed remarkable advances in the methods employed in carrying on various industrial operations. Of these none, perhaps, are more striking than those having to do with handling material.

One remembers the old days when great gangs of men were necessary for handling almost any kind of work, because labor saving devices had not yet come into general use, nor were many of them perfected as we find them at the present time. Cars were loaded and unloaded by wheelbarrow gangs. Charging boxes, around the furnaces, were loaded by hand. To 'put over' a job, it was of first importance to secure an adequate force of men, and then followed the necessary hand equipment—just the reverse of present methods, which give first consideration to what equipment to use and then to the men who will operate it.

This paper by Clarence E. Ralston, Equitable Life Assurance Society was read and discussed at Eleventh Annual Safety Congress held recently in Detroit.

Old Methods—Frequent Accidents

With the recollection of the large gangs of men we also recall the dark side of the picture, the frequent accidents among them. Many such accidents causing serious injuries, are now considered preventable and entirely unwarranted.

Lack of proper equipment was responsible for much wasted labor and the lack of proper interest on the part of the supervisors was responsible for even a greater waste, through the methods used. Properly trained supervisors or trained men were not given much consideration and, in fact, in many cases, were never even thought of. The one consideration seemed to be to get the cheapest labor possible for such work, regardless of the nature of the material to be handled.

The two causes of waste were just as truly the causes of the many accidents which occurred, as has been clearly demonstrated where the accidents were carefully analyzed to determine the real cause. Where proper consideration has been given to these two causes, the accidents have been greatly reduced and in some cases practically eliminated.

Conveyors, Magnets, Trucks

The old time methods of handling work are fast going into the discard and whether it be on construction work, from the excavation to the completed project; or the operations in various industries, from handling the raw materials to the shipment of the finished product; or the transportation of goods, from the loading to the delivery, we find wonderful progress in all lines. Conveyors and hoists have supplanted the wheelbarrow gangs; electric magnets have taken the place of the laborer in the scrap-yard and around the charging boxes; power-operated trucks have replaced the old hand-trucks. Numerous other mechanical and electrical appliances of like nature might be added to the list.

Consideration is now given, not only to equipment for the safe and efficient handling of materials, but to men and methods as well. With the consideration of methods comes first the trained worker, including both the supervisor and the man in the ranks.

Much of this great change is due to the natural growth and development of industry, but one of the most important factors has been the great safety movement. Through the study of the causes of waste through accidents have come many developments which might otherwise have been long delayed.

Accidents due to handling material have been for years entirely too frequent, in fact they are appalling. To this general cause can be charged a greater loss than to any other, yet it is not the difficult and unsolvable problem which many have credited it with being. It is only one challenge out of many which confronts the safety engineer. Whenever and wherever a definite study of the problem has been made and this followed by a well planned campaign, the hazards have been eliminated and the accidents due to this cause greatly reduced, if not entirely eliminated.

Lack of Supervision

This recalls to mind an instance during the World War which illustrates the point, particularly as it relates to one phase of transportation. The U. S. transport "West Indies" called at the Mare Island navy yard, California, for a cargo of 12 in. x 12 in. timbers which was very much needed at the Norfolk navy yard on the Atlantic coast. The shipment was quite large— over 2,000,000 ft. of timber—and orders had been issued to load the vessel with all possible speed as each hour meant just that much delay in getting the timber where it was needed. The loading of a cargo vessel, with all the loose rigging with which such vessels are equipped, is no child's play, and shortly after the work was started, a man was knocked overboard and severely injured. The investigation of the accident which was made immediately, developed two glar-

ing conditions—defective hooks on some of the rigging, although this was not the cause of the accident, and inadequate supervision, as all the hatches were being loaded at the same time. The defective hooks were replaced at once and a **force of supervisors** distributed over the deck of the vessel in order to observe the work at each hatch. There were no more accidents of any kind and the vessel was loaded and started on her voyage in record time.

Handling Accidents Come High

A glance over the accident records of the State of Wisconsin for the year 1920 reveals some very interesting data concerning this matter. During that year there were 16,246 compensable injuries and of this number 3,533, or 21.7 per cent. were charged to handling objects—more than those charged to any other cause. The Severity Classification of the injuries places this cause as 5th in time lost: 3rd in compensation cost and 2nd in medical cost.

One large steel company reports handling material as the cause of 48 per cent. of their accidents during the year 1921 while another holds it responsible for over 40 per cent. of their accidents during the last six years.

With these facts before us, I am sure we are all agreed that a concerted move must be made to eliminate the accidents due to this cause. From my own personal experience, I am fully convinced that the key to this problem will be found in the supervisor. He must first be taught to **plan his work and then work his plan.** Next must come the worker in the ranks who must be taught to think as he works—not of some foreign subject but of his work—how and why he is doing it.

The supervisor is responsible for methods, the condition of equipment and at least part of the training of the worker. After planning his work, his next move should be the careful selection and placing of his workers. They should be placed according to both physical and mental fitness as far as possible. Too much cannot be said of the importance of this part of the program as a "misfit" will cause the failure of the most carefully developed plan—he is the weak link in the chain.

The training of the workers can be done in several ways in order to be complete and effective. The training by demonstration must be done through the supervisor on the job, while the training by illustration will come within the duties of the safety engineer or director. This latter training should be through the use of lantern slides and other pictures, showing very clearly how to do and how not to do the work. These pictures can be analyzed with the men in small groups and through such group meetings their personal interest will be aroused and held. This method was used at the Mare Island Navy Yard, California, during the war and I am convinced was a big factor in enabling us to reduce the accident rate 86 per cent. in the face of a 116 per cent. increase in force and this during a 16 month period. Such training will not only decrease the accidents but will greatly increase the efficiency of all concerned—**thus giving us a three-fold profit from safety work, 1—Lessened waste through accidents and compensation costs; 2—Increased production, and 3—Lessened costs of production.**

Careful training of men along these lines will gradually bring them to that understanding which is so much to be desired in Industry—that they are working with their employer and supervisor to accomplish that which society expects of them, and not working for the employer or supervisor.

The supervisor must be made to realize that he is the personal representative of the employer and that it is his duty to see that the working conditions are safe. He must also realize that losses through accidents are an indication of his inefficiency and that the workers must be protected even better than the equipment, which can be replaced without any physical suffering. It is not to be supposed that he will personally inspect all equipment and conditions, but he should select competent men for this purpose.

CANADIAN MADE SNIPS AND BENCH SHEARS

It will be interesting to the trade to learn that sheet metal snips and bench shears are now being made in Canada. Many imported tools of this character are hand ground and it is difficult to obtain blades with the edges parallel, a condition that is necessary to retain a keen cutting edge.

The Brown, Boggs Company, Ltd., Hamilton, Ont., manufacturers of tinsmiths' tools and sheet metal working machinery, have installed special machinery whereby they claim they are able to produce a shear, machine ground, giving that smooth cutting edge not possible with hand grinding. In grinding them in this manner it is rightly claimed that the edge will last longer. The forgings are of the best steel, correctly designed, well made, and the cutting surface overlaid with Jessop's best cast steel. Great care is exercised in the tempering, which is scientifically done by the assistance of lead and oil baths, and pyrometers. The finish is also carefully looked after. Some few years ago the company manufactured snips in a small way, but since their severe fire in 1916 they have had these articles manufactured in the U. S., under their name. Their inability to obtain a satisfactory shear compelled them to resume their manufacture, and to install a special plant for that purpose, and to distinguish between the U. S. and their make, they are now marking the new product "MADE IN CANADA" and will thoroughly guarantee every pair.

They are also making bench shears, machine ground, and giving them the same careful attention as they do their snips. In bench shears the difference between hand and machine grinding is much more apparent, on account of the large cutting surface. It is almost impossible to cut true to a line with hand ground bench shears, the shear following the contour of the blade. The company is certainly to be congratulated in the splendid results in this new line of manufacture.

Jigs and Fixtures for Producing Lathe Parts

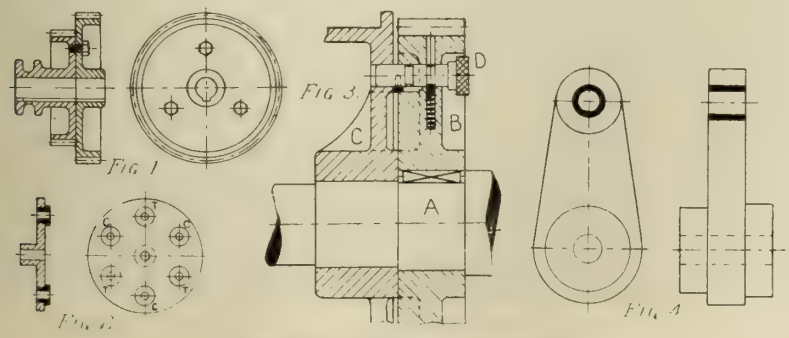
Drilling Holes in Duplex Back Gears—Locking the Drive Cone in Position—High Speed Steel Reduces Actual Cutting Time—Fixtures Used to Speed Up Production—Special Angle Plate

By HUBERT BENTLEY, A.M.I.M.E.

THE accompanying drawings show some common lathe details and the jigs and fixtures which are employed for ensuring accurate and rapid production, of the holes to be drilled. Fig. 1 is a drawing of the duplex back gears for a lathe driving headstock, which are made to slide on the back barrel or sleeve and to engage with their mating gear on the spindle, and thus obtain two different gear ratios. These gears may be moved directly by hand or they may be operated by a lever working in the groove shown and actuated by a hand lever at the front of the headstock. The method shown of securing the two gears together by means of three set screws is both simple and satisfactory, and Fig. 2 shows the jig employed in the drilling of the screw holes. There are three holes to drill in each gear. The holes in the larger gear are ⅝ ins. clearance holes while in the smaller gear there are ⅝ ins. tapping holes. The gears are drilled separately with the flat face uppermost. The jig plate is laid on the top with the turned boss fitting inside the hole in the gear and the whole is made secure to the drilling machine table by a clamp plate and bolt which passes through the centre of the jig plate and gear. Of the six hardened steel bushes which are fitted equidistant around the jig plate, three are drilled for clearance holes and three for tapping holes and these are marked respectively C and T. When the two gears have been made secure by the screws they are then ready for the keyway to be slotted.

Spring Locking Bolt

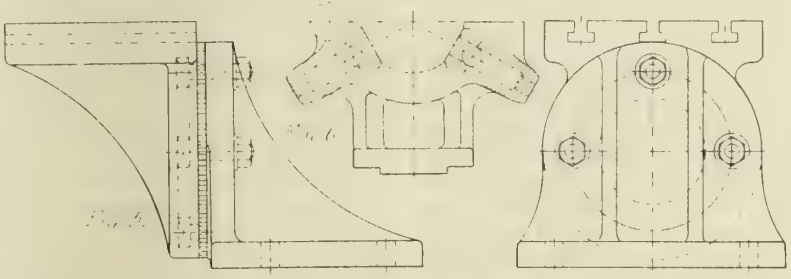
Fig. 3 shows a very simple and successful spring locking bolt employed for securing or releasing the driving cone and the main spindle gear wheel when a lathe is being run on single or double gear. The advantage of this type of bolt over the ordinary hexagon nut and bolt will be familiar to readers. A shows part of the spindle, B a section of the main spindle gear, C a part of the driving cone and D the locking bolt. When the locking bolt is out of engagement with the cone, this is free to revolve around the spindle, but when engaged as in Fig. 3 the cone and gear wheel revolve together. An inner as well as outer flange is arranged on the cone at the large end and this is connected to the boss by three webbed arms. Three holes are drilled in this flange on the arm centres for receiving the locking bolt which is made of high tensile steel. In the main spindle gear a solid strip is cast connecting the rim and the boss which supports the bolt close up to the cone. A strip cast diametrically opposite in the gear helps to maintain the balance. To disengage the locking bolt, this is pulled outwards. There are two circular grooves turned around the bolt which receive a spring operated ball seen on the underside, when the bolt is in the respective "in and out" positions. This causes a little pressure to be exerted when changing positions. The hole for the spring and ball is drilled between two teeth in the gear wheel. A small key in the locking bolt and keyway in the spindle gear prevents the locking bolt moving too far in either direction. By having three holes drilled in the cone flange, engagement can be quickly made, when pressure is applied to the locking bolt. Fig. 4 shows the jig employed to facilitate the accurate drilling of the holes in both the cone and gear wheel. The smaller turned boss is made to fit the cone bore and the jig is moved around in succession to the three positions of the holes in the cone flange. The jig plate is secured to the cone by a bolt through the centre. For drilling the single hole in the spindle gear, the larger turned boss is fitted in the gear wheel bore. The drills are guided by a hardened steel bush fitted into the jig plate.



Construction of different lathe parts.

Cutting Time Reduced

Due to the old-fashioned methods so often employed when fixing and changing work on the drilling machine, a record of the actual machine running times, would show these to be a very small proportion of the working day. This would be most marked where the employment of high speed steel makes the actual cutting time of very short duration. The provision of suitable means for quickly handling and changing the work to be drilled now appears to be receiving more attention and there are a good variety of angle plates, machine vises and work tables, which swivel in one or more directions, on the market. They are suitable for application to many other types of machine tools as well as the drilling machine.



Adjustable angle plate and steady rest.

Special Angle Plate

The swivelling angle plates shown in Fig. 5, in elevations, were designed specially to facilitate the drilling of holes in two and three paw travelling and stationary steady rests of the type shown in Fig. 6. It will be recognized that an ordinary swivel machine vise is too small for the job, while a universal tilting table was considered too large and expensive. Hence the design of the cheap but very effective angle plates shown, which it was intended should also be available for other jobs. The angle plates enable two or more holes to be drilled at various angles in the same plane without removing the casting until the job is completed. The two plates are spigoted together on their vertical faces, turned circular and secured by three bolts. These bolts fit in a circular tee slot cut in one of the vertical faces and so enable the other plate to be swung round in a complete circle and to be made secure in any desired position. Graduations in degrees are cut on the periphery of the rotating member to facilitate quick setting to any angle.

Heavy Labor in Demand-Skilled Workmen Scarce

Active Season in Lumbering Industry and Railway Construction —Five Thousand Bushmen Wanted Where Few Hundred Men Hired in 1921—Machinists Fairly Busy—Market Absorbing Highly Trained Men

HEAVY LABOR, scarce; farm help, scarce; skilled labor, building trades, scarce; machinists, fairly busy; boys scarce after Sept. 4. This sizes up the labor situation at the present time. Considerable demand for heavy labor is coming from lumbering and railway construction work. Not all men are adapted to this kind of work and there has to be considerable weeding out among applicants to meet the requirements of contractors.

Wages range from $30 to $35 monthly, everything found. An indication of the extent of lumbering activities this fall is the fact that the government employment service hopes to recruit 5,000 men from the Toronto district alone. Last year there were probably not more than 300 men placed from this source. This means that large cuts of lumber are in prospect and that the huge stocks of one and two years ago are being depleted. Activity in the building industry is undoubtedly having its effect and here again the condition of the labor market may be regarded as a barometer for there is scarcity of bricklayers, plasterers and carpenters.

When Seasonal Work Stops

Operations calling for much heavy labor will help to absorb many of those who may be allowed to go when seasonal work comes to a close. There are 1,800 men employed by the Toronto Transportation Commission. With the coming of frost the majority of these men will be out of work. The same applies to men on Welland canal work.

Some ten thousand men were drawn from the Toronto district for work in the western harvest fields. Eighty-five per cent. of these men will have returned by Nov. 1, but quite a large proportion belong to farming communities and will thus be readily absorbed. Some success is attending the movement to have farmers hire their men by the year. In not a few cases separate houses and plots of ground are being provided and a fair attempt put forth to make the lot of the hired man contented. Strange as it may appear, more progress is being made in this direction in Western Ontario than in the East, the explanation probably being that in the former there is a greater percentage of larger farms.

Good Mechanics May Be Scarce

That machinists are only fairly well employed, suggests conditions as they exist in the metal working industry. The motor car industry is running into a breathing space between seasons and some men have been let out. Full time has not yet been inaugurated generally as a regular proposition. The high-class skilled mechanic will have little trouble in securing work at the present time, however, for the market has reached that stage where it realizes that the time may not be far distant when good men are going to be scarce. Many machinists have preferred to work on other jobs this summer, claiming conditions in their trade are not acceptable.

Scarcity of boys after Sept. 4 is explained by the fact that school re-opens following Labor Day. Hundreds of boys have been industrious during the holidays and these include all classes from those whose clothing and demeanor stamp them as coming from good homes to those who, no less full of pep and quite as reliable, reflect less favorable living conditions. There are those too, who, to an extent representative of both classes, follow lines of least resistance and take a more or less indifferent view of life, evidently preferring to take circumstances as they come rather than develop a dormant ambition.

Demand for High-Class Men

All sorts and conditions come within the scope of the government employment service. In the Toronto department, for example, there are one thousand applicants for work who can only handle light or special tasks, some in fact who are only able to work a few hours each day. There are elevator men and those who try to piece out two or three jobs of a certain type in order to produce somethng like a full day or week. There are men who do cleaning of various kinds, men who prefer to work nights and those who are more or less temperamental as to their hours of service during the day. One man wanted a job in a restaurant. He was asked "What can you do? When do you want to work?" "Anything, anywhen, so long as it is near the food," was the reply.

Not a few highly-trained technical and professional men are among the applicants. Not long ago a mechanical engineer, who had never drawn less than $5,000 a year, was listed. His name was placed on the bulletins going to seventy-six employment offices and immediately there were replies, one from Oshawa, one from Winnipeg, one from St. John, N. B., and several others indicating a market for just such men. He was easily placed. Very recently a large concern wanted to import a production engineer from the States. The department makes this possible after certain formalities have been complied with. In this case, however, a Canadian was found for the position as a result of the listing and bulletin service. It is pointed out by officials that this placing of high-class men is having remarkable development. The work is done in a thorough, considerate and dignified manner, numbers being used, with careful descriptions in listing the applicants, and in this way many avail themselves of the service who might otherwise be repelled. And there is quite a market at present for well-trained, competent men in Canada.

Consideration for Employees

A manufacturer of machinery gives the following minimum and maximum rate of wages paid by him at the present time. Machinists, 50 to 70c per hour; Machinist laborers, 30 to 43c per hour; moulders, 60 to 72 per hour; moulder laborers 40c an hour; pattern makers 65 to 70c per hour; pattern shop laborers, 35 to 45c per hour; crane men, 35c to 42c per hour.

This particular manufacturer made a general reduction of 10 per cent. in wages early in the year. He adds:—"There are not enough jobs to go around, and men have been working on such short time that it has not been possible to make what is really necessary in the way of reduction of wages owing to this short time. It is hard to say what the tendency will be a little later on.

"If, business was offering sufficient to run the plant to capacity, it is possible that the increase in production over the present time, would make it possible to produce goods at a reasonable profit even at present price of wages. At the present time, our machine tool plant is operating more with the idea of holding the organization together than with any possible idea of profits, and we believe that we are one of many plants in the iron business who are operating on the same lines. We have been trying to carry on with a view to helping out the men as much as possible, and for this reason the matter of any further reduction of wages has had to be held in abeyance. Under present rates, with the very short time our men are working it is almost impossible for them to make it go financially, and although manufacturers, as a rule, are not given credit for having very much of the milk of human kindness, you know and everybody knows that consideration for the employees under present conditions is the dominating feature in the wage situation."

Wages 11 Per Cent. Higher

Higher by 11 per cent. than those of 1914 are wages throughout the country, according to the bimonthly summary of industrial economic conditions issued by the National Conference board.

A summary of wage changes by months shows fifty-four reductions and

(Continued on page 53)

Production Milling on Two-Spindle Machine

Jigs Should be Simple and Efficient—Conveniently Operated When Machine is Working—Keeping the Cutters Engaged Continuously—Roughing and Finishing at Same Time Means Economy

WHERE METAL parts are to be manufactured in reasonably large quantities a question of primary significance is the selection of the most suitable equipment for performing the machining operations. The rapid development of modern machinery makes it imperative for the superintendents of most plants to study carefully the different angles by which any mechanical problem can be attacked and economically solved. The methods that were successful in doing a certain piece of work five or ten years ago, may, at the present time, be entirely inadequate to meet existing demands. Not that the past practice is less efficient in itself, as in many instances the rate of production has shown steady increase over what was possible years ago. This has been made possible through the introduction of high speed steels and their greater ability to stand up to heavy cuts for longer periods.

However, when the question of maximum production is the point on which a decision is to be made the choice invariably falls to a selection of a tool that has been especially designed to meet specific requirements. It is seldom necessary to have a machine tool built for the machining of a single part, but the general range of any standard type of machine, gives ample opportunity of obtaining one that is 100 per cent. effective for a variety of work within its capacity.

Keeping Tools Engaged

The secret of increased output is not so much in speeding up the actual cutting time occupied by the tools in removing metal, but rather in reducing the idle time that features many of the machines of a decade ago. The aim of the tool designer, to-day, is to provide facilities whereby the cutting tools can be operated continuously. Few tools have shown greater possibilities in this direction than the vertical milling machine. The multiple cutting faces of the milling machine cutter permit of the removal of metal more rapidly and smoothly than by any other means. The adaptability of this tool is so varied that work formerly performed on shape planers, slotters, etc., can be more effectively handled in one of the many different types of horizontal or vertical milling machines.

The possibilities of the rotary table in conjunction with multiple spindles is shown in the accompanying illustration. The character of the work and the machining operations necessary are the governing factors in determining the designs of the work holding fixture. With few exceptions it is advisable to make jigs as large as conditions will permit, as in this way the presence of slightly curved surfaces will be less pronounced. Rigidity and simplicity are points of vital importance as vibration of the work under the cutting action of the tools prevents the utilization of heavy feeds and high speeds, and likewise affects the life of the tool, tending to destroy the cutting edges much sooner than when working under ideal conditions. The method of holding the work should be simple and effective, and convenient means provided for clamping the pieces in position.

Simple Jig Construction

In the construction of jigs and fixtures, efficiency is of first consideration, but as the cost of any device of this character must be carried by the particular job it is made for, it is advisable to make it as universal as the nature of the part will permit. It is often possible to design a fixture where the clamping section is distinct from its base which is used for securing to the revolving table. A little study should enable suitable work holding rings or regular sections to be secured to a standard base, thus lessening the initial cost of the fixture. In this way several top jig sections may be placed in position on the one permanent base.

Facing and Chamfering

The fixture illustrated in Fig. 1 shows a double-spindle vertical milling machine at work on automobile thrust blocks. Four cutters are used on each spindle, those on the rear spindle being spaced to mill the flats, while the cutters on the near spindle are arranged for beveling the edges as shown. It will be noted that the base of the work-holding fixture has six raised posts upon which the jig proper is located and held in position by a suitable cap screw in each of the six supports. It may be seen that the fixture is of the multiple duplex type where two rows are operated on at the one time. The clamps on top and bottom are similar, the bolt passing completely through with coil springs inserted to free the clamps from the work when the pressure on the clamps is removed. These thrust blocks are produced at the rate of 400 per hour.

Roughing and Finishing

The operation shown in Fig. 2 consists of machining the fork ends of gear shifting yokes. In milling these forgings the cutters on the rear spindle are

Introducing

JAMES GARLAND,
Supt. Dominion Engineering Works

MR. GARLAND comes from an engineering family, having served his apprenticeship in the shops of Henry Disston & Co., at Taconey, Pa. Upon the completion of his apprenticeship, he entered the shops of I. P. Morris & Co., at Philadelphia. At this time the development of power at Niagara in a large way, was just commencing. The Morris shops were building some of the first large turbines, and Mr. Garland's duties kept him in close touch with this work. He was soon given outside work erecting and installing machinery built in the shops. This work took him all over the Southern States, Porto Rico, Cuba, Mexico and Central America. A large number of sugar mills were installed in these countries by him, and in five years spent at this work he picked up a good knowledge of the Spanish language. Two revolutions occurred in Mexico while he was located there. The last one caused him to hastily vacate the country. Following this he was employed largely in installing hydro-electric units, having been engaged on some of the largest developments in the United States and Canada. Among the Canadian plants that he supervised are several of the installations at Niagara, the Cedar Rapids developments and installations at Shawinigan falls.

Mr. Garland was located at the Cedar Rapids plant when the war broke out. He was placed in charge of the Shawinigan Power Company's Acetone Plant at Shawinigan Falls. He superintended the installation of all the machinery and operated it throughout the war. This work was very strenuous, as fires and explosions were numerous. When the armistice was signed he went back to the I. P. Morris Co. as general inspector. In November 1920 he accepted the position of superintendent of the Dominion Engineering Works at Lachine, Que., in which capacity he is now employed. He came to Canada in 1904 and his first work was to install a 10,500 h.p. turbine at Shawinigan Falls. At that time this turbine was the largest powered turbine in the world. Only recently Mr. Garland built in the shops of the Dominion Engineering Works, and is now supervising the installation of, a 41,000 h.p. turbine. The case for this wheel was the largest steel casing ever made.

He is a member of the American Society of Mechanical Engineers. His chief diversion is motoring and during the season be puts his McLaughlin over several thousands of miles.

Fuel Oil In Growing Demand As Substitute For Coal

THAT THERE is an increasing demand for fuel oil for heating purposes, as a substitute for coal, is the statement made at headquarters of oil companies who are equipped to supply requirements in this field. There are already quite a number of large buildings in Toronto using fuel oil, chief among those of a public character being Osgoode Hall, and it is likely that, as a result of coal problems, the number will be increased very considerably this fall by public buildings, industrial plants and private dwellings. The persistency with which trouble each year associates itself with the coal supply causes a multiplicity of enquiries each season. Some of these install oil burning apparatus, but the great majority, on considering the initial cost, generally decide to pay the shot and continue with coal, hoping for the return of easier prices.

"It is this initial cost which causes much of the hesitancy in installing fuel oil," said the engineer of an oil company to Canadian Machinery. "In converting a heating system, the tank in which to store the oil is a big item. For private dwellings it is a mistake to install a one hundred gallon tank as some do, because this has to be filled frequently, as a rule, from barrels, and this in time becomes a nuisance. By installing a 1,000-gallon tank the problem is solved probably for the season, or, if not, a refill may be made direct from an oil wagon. The large tank may be placed underground outside and the oil is forced into the burners by a very small pump. There is no dust, no dirt in the cellar and no ashes to remove, and the lighting of the furnace becomes an exceedingly simple matter. We generally figure that one hundred and ten gallons of oil are equal to one ton of coal. This amount of oil at present prices would run about $11. It is thus seen that there is some margin in favor of oil at present prices and Osgoode Hall has a 10,000-gallon tank. This building burns, on an average, about 200 tons of coal in the winter season. Their tank would have to be filled twice in a season, depending on what was carried over as a reserve. In a large plant, when you consider the cost of handling coal and ashes, the help required in the furnace room and the dust which comes from that place, there is much to be said in favor of fuel oil. The same applies to private dwellings. In the planning of a new building the heating method very often calls for consideration of other fuel besides coal. An increasing number of engineering firms are devoting their attention to this problem."

From New York the report comes that fuel oil is becoming increasingly popular as a means of heating large office buildings but that engineers do not expect to see oil eliminate coal, as there is not sufficient low grade Mexican fuel oil in sight to supply such needs. Tankage, it is estimated, represents over 50 per cent. of conversion costs, but many residences in New York's suburban districts, where costs are not so high, are making the change.

Estimates of boiler efficiency in public buildings and industrial plants differ. One engineer states his hand-fired boilers formerly averaged 54 per cent. heat efficiency burning coal and about 78 per cent. heat efficiency at present with oil. Mexican fuel oil averages about 18,000 heat units, while coal runs between 11,500 and 12,000 heat units to the pound.

Owners of one of the big buildings using oil find considerable saving in cost of fuel and labor compared with coal. This building uses 1,640 gallons daily of 16-Beaume Mexican fuel oil at 4½ cents a gallon, a total fuel cost of $73.80 a day. When oil-burners were first installed 2,400 gallons daily were used, but increased efficiency reduced consumption.

Formerly this building used 15 tons of coal daily costing, at present quoted price of $15 a ton, $225 a day. At a normal average of $7 a ton, fuel bill would be $105 a day. In addition it has reduced its fireroom force from 14 to 10, a saving of $100 in labor. On top of this is elimination of ash removal costs which differ to the extent of ash content in coal used. Experience of management of this building was that its coal contained 17 per cent. ashes costing $180 a month to remove. Replacing old cans cost $100 a year, so that by eliminating items of ash removal and new cans annual saving of about $2,300 has been effected.

Other buildings and plants which used more coal have effected greater savings.

Practical Ideas From Practical Men

TAKING STRETCH OUT OF VERTICAL BELTS

By W. F. Schaphorst

Vertical belts give more trouble than others, because of the fact that as soon as the belt stretches, contact with the lower pulley is lost, and the power will not be transmitted. In the horizontal drive, stretch is easy to take care of, provided the belt is kept soft and pliable, with the right kind of belt dressing that not only dresses the surface but that penetrates, surrounds and lubricates every tiny fibre. It then becomes unnecessary to take up horizontal drives at all. Many drives are in daily use which have not been taken up for 18 years or more, and then they were taken up only because the belt became so slack that the slack side touched the tight side. Extreme slackness is as impractical as extreme tightness.

Where vertical drives are used, it is obviously impractical to permit slack running because it is necessary to continuously take up the belt stretch as the stretch occurs. One successful and economical method that has been brought to the writer's attention to constantly keep vertical drives in pulling condition is to have a number of "fillers" or "inserts" in stock already punched to match and ready for insertion and lacing. Thus, it is cut short by an amount depending upon the distance between the shaft centers. The belt man uses his judgment as to what this short cut should be. Let us say that he desires to make it 1 inch. He then selects a filler 7 inches long, of the same width as the new belt, and laces it into place either with rawhide or wire lacing.

In a short time the belt will stretch and will need taking up. The belt man then simply removes the 7-inch filler and replaces it with a 6-inch filler. After another week say, he replaces the 6-inch filler with a 5-inch filler, and so on until all of the stretch, or most of it, is taken out of the belt. The fillers can be kept in stock and used repeatedly. In this way there is no loss of belting material for example, when a belt is put on new due to taking up, nor is there any time lost due to the punching of new holes as they are already punched in the fillers. The writer does not recommend this filler method for horizontal or sloping drive, because he is a believer in the slack or easy drive, which gives a maximum arc of contact between the belt and pulleys, least bearing friction, and highest transmission efficiency.

MACHINING AIR COMPRESSOR PARTS

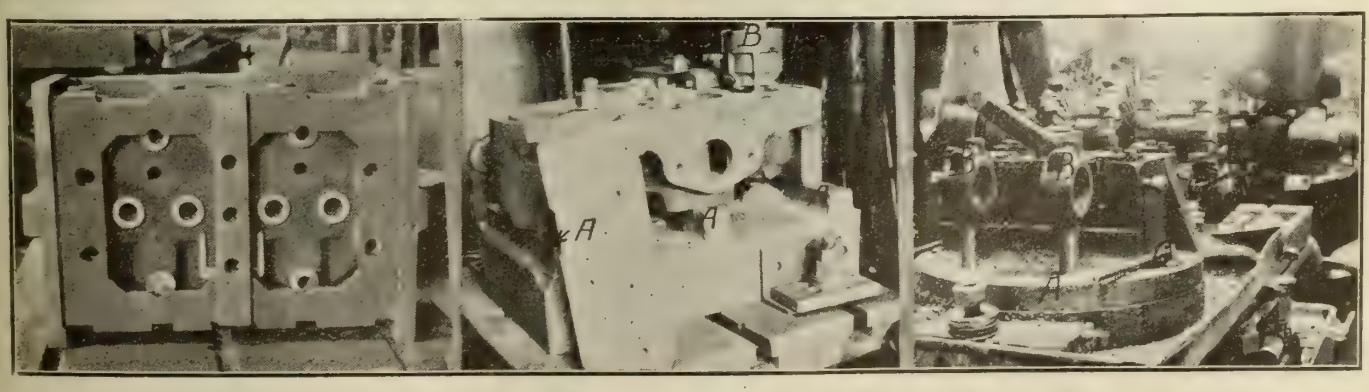
By Robert Mawson

The first operation on the compressor cylinder head here shown is the milling of the joint face used to attach the head to the cylinder. The casting is then placed into the jig shown in Fig. 1, being placed with the machined side down and held in position with the cover, which is fastened to the jig body by means of two wing screws. The jig cover is placed in the proper location in regards to the body, with two dowels at the opposite corners to the screws. A set screw then forces the piece back to the locating pin to bring the casting in the correct position for drilling. All the holes are then machined in the cylinder head for the holding down bolts, manifold screw holes, valve guide and spark plug holes. Guide bushings are provided in the jig for accurate and interchangeable production. Fig. 1 shows the jig turned on its edge, in position for drilling the holes for the manifold screws.

Fig. 2 illustrates the tool and method used to machine the valve seats of the cylinder head, which is the next operation. The casting is placed on the fixture shown, being located with the three machined pads A, the fixture resting on the drill table. Straps are used to hold the casting securely in position on the fixture. The special tool B is then fed into the valve chambers and this boring tool is provided with a pilot bar which fits into the valve guide holes machined in the previous operation. The boring bar B is made with six inserted cutters and it will be noticed that these are provided with bevelled edges or ends of 45 deg. The operation of feeding the bar down into the casting, therefore, machines the valve seat to the proper angle and the upper portion of the blades bore the valve chamber to the correct diameter. After the bar has been passed down once to the proper depth, which is determined by a stop on the machine, the bar is raised and transferred to the next valve opening and the operation repeated.

The next operation is grinding the valves into position, and for this work the valve is placed into the valve chamber after a portion of grinding compound has been placed on the bevelled seat. The valve is then oscillated on the seat until a good bearing is obtained. All four valves are treated alike and then marked to their proper positions where they were ground so that they will be placed in the same valve chamber when assembling the motor.

Fig. 3 shows a special fixture used when milling the large ends of the connecting rods. The forgings are located in the fixture by means of slots into which the small ends of the rods fit, these slots being in the plate A. The fixture is designed to hold four rods, two at B and two located in a similar manner directly opposite at the rear of the fixture. Four cutters correctly spaced are fastened on the machine arbor as shown and the machine table being fed along both sides of the connecting rods are machined. The machine table is then brought back out of the range of the cutters and the index pin C removed. The upper portion A is then revolved 180 degrees and as the moving portion of the fixture is provided with a register fitting in a machined recess in the fixed portion D the sliding element will move easily and in a concentric manner. The two connecting rods B are now in the proper location for the machining of them and the fixture is again located with the index pin C fitting in another hole 180 degrees from the former location and the rods are machined in a manner similar to that described for the



Jigs used in machining cylinder heads and connecting rods.

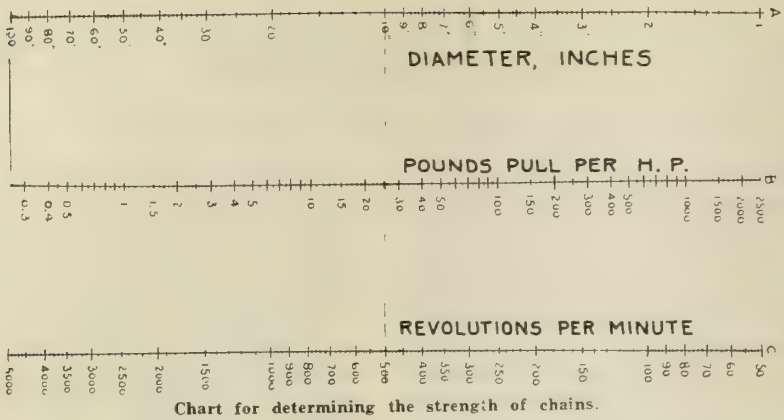


Chart for determining the strength of chains.

two rods previously milled. The advantage of this style of milling fixture is that the operation is practically continuous as while the machine is milling two rods the operator is placing another two rods into the fixture ready for machining; the only lost time being the revolving of the fixture between the milling operations.

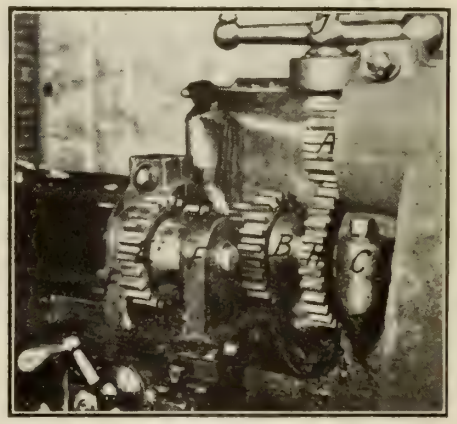
RUNNING-IN MACHINE FOR AUTOMOBILE TRANSMISSIONS

It is well known that gears which are intended to run together at any high rate of speed scarcely ever operate smoothly and silently. This is so through a number of causes; limitations in machining methods, even when these are the most modern as regards tools and manner in which the piece is held for the machining operation. If they are hardened we find that they will change in tooth outline and shape and will produce this unevenness of tooth contact.

To correct these faults the Premier Motor Co., Indianapolis, Ind., have designed and use the machine shown in the illustrations Figs. 1 and 2 to run together their transmission gears to obtain a smooth operating train. The driving gear of the set A is fastened to the driving shaft of the machine, the train of speed change gears is mounted on the same shaft that is used in the transmission and shown at B. This shaft is supported in brackets at each end C, at the opposite end to the driving gear being the other constant mesh gear D. Meshing into this latter gear is the gear E held on a shaft, supported in brackets, F.

The purpose of this machine is only to run-in the constant mesh gears, the sliding gears being made so they can be moved along the shaft and into mesh without friction. The gear E is brought into the proper tooth contact by means of the handle G which moves along the bracket holding the forward gear through the medium of a screw. The gear H which meshes with the driving gear is brought into tooth contact with the handle J which moves the bracket C up or down as desired until the proper engagement of teeth is obtained.

The obvious procedure is to adjust the gears A and H first and then set over the slide carrying the gear E. When the gears have been set, abrasive is placed onto the teeth and the machine started in operation until the gear teeth run together smoothly and silently. If the gear outlines are very much out of alignment the adjustments should again be made, bringing the gears further into mesh and the running-in operation repeated. This is often done at the plant as gears after the first running together will show too much back lash



Running-in Motor Transmission

and a smooth operating train with proper tooth contact can only be obtained by one or two adjustments and then running the gears together until the desired result is reached.

HOW MANY POUNDS PER HORSE POWER?

By W. F. S.

The accompanying chart will solve a multitude of problems that ordinarily are vexing indeed. All you have to do is—lay a straightedge across and there's the answer in the middle column. For example, I want a chain for a 10-inch sprocket running at 500 r.p.m. to transmit one horse power.

The dotted line drawn across the chart shows how it is done. Connect the 10-inch (column A) with the 500 (column C) and column B gives the answer immediately—25.2 pounds. In case a chain is wanted that will transmit 10 h.p., you would just multiply the answer by 10, which gives 252 pounds as the necessary strength. In the case of a belt drive, the chart can be used in the same way for determining "effective pull"—the difference in tension between the tight and the slack sides. For rope drives the effective pull is found in the same way. In other words, the effective pull on a 10-inch rope sheave running 500 r.p.m. must be 25.2 pounds in order to transmit one horse power. Knowing the effective pull, then, we can tell the manufacturer just how strong the chain, rope, belt or cable must be.

Whether the transmission medium is round, flat, square or triangular makes no difference. It must be "just so strong," and this chart gives the strength. Generally, after figuring the exact pull, we multiply by a factor of safety in order to be "sure" that the belt, or whatever it is, won't break. The factor of safety is "up to the designer."

LEVELLING WITH A HOSE FULL OF WATER

By W. F. S.

Not long ago I wrote an article describing a method of leveling by simply filling a hose full of water. Then by means of gauge glasses inserted into each end of the hose the exact level can be readily noted. This is an exceedingly good method for leveling shafting, foundations, floors, beams, etc. I am in receipt of a communication from a Californian who criticizes the method. He says he found it very hard to do. It occurs to me that my reply, which follows, may be of some value:

"I had a similar experience at first but I found that the best way to handle the hose it to keep one end fixed and to simply move the free end around. It is true that the job is a difficult one for one man although I have done it alone. However, I did not have any difficulty in getting the same results twice and cannot understand at this distance why W. S. should have difficulty in that respect. However, it may be that air got into the hose in which case a difference of levels would register or if there should happen to be a residue of oil or some other liquid in the hose the specific gravity of which might be less than the specific gravity of water such things would also influence the level and would make it absolutely impossible to do an accurate job with this kind of a level. Also now that W. S. has brought up the subject it occurs to me that a difference in temperature at one end would also influence the level but I believe such great differences in temperature seldom exist. However, if one end should be kept for any length of time near a radiator or near a steam boiler there would be considerable danger of differences in levels and the results certainly would not be reliable.

"The method of corking up the ends while moving the hose is all right, also the method of using valves instead of corks is all right, but during the leveling or after arriving at a point that is almost level the corks should be removed or the valves should be opened so that there will be no air pressure above the water level. The air pressure would, of course, tend to throw the water out of level."

New Things in Shop Equipment

BROACHING MACHINE

A new high-speed hydraulic broaching machine which is claimed to be capable of handling from 75 to 200 per cent. more work than any single or double-pull broaching machine of the usual type. The reasons for this increase in productive capacity are to be found in the higher speed available (360 inches per minute maximum), in the practically unlimited choice of speeds, and in the automatic control of the cutting and return strokes entirely independent of each other. Another advantage of the new machine is the decrease in the unit labor cost. The time required for a completed piece varies from 15 to 20 seconds, depending on the particular work to be done. Numerous tests have also shown that the unit power cost is lower than on other types of broaching machines. The overall efficiency is high, ranging from 70 to 90 per cent. No power is wasted in clutches, gears or screw drives.

The following actual production figures are typical of those that are being obtained on this and similar work. The work consisted of broaching four solid keys in a differential bevel gear, 1¼-inch bore, 2 inches long, and made of .22 carbon steel. The cutting speed was 288 inches per minute and the return speed 312 inches per minute. There were two broaches in the set and the draws per hour averaged 145. The maximum horsepower required was 5½ for a cutting time of 6½ seconds. On the same work, a screw machine produced 80 draws per hour. The cutting speed was 80 inches per minute. The maximum horsepower required by the screw machine was 8 for a cutting time of 23 seconds.

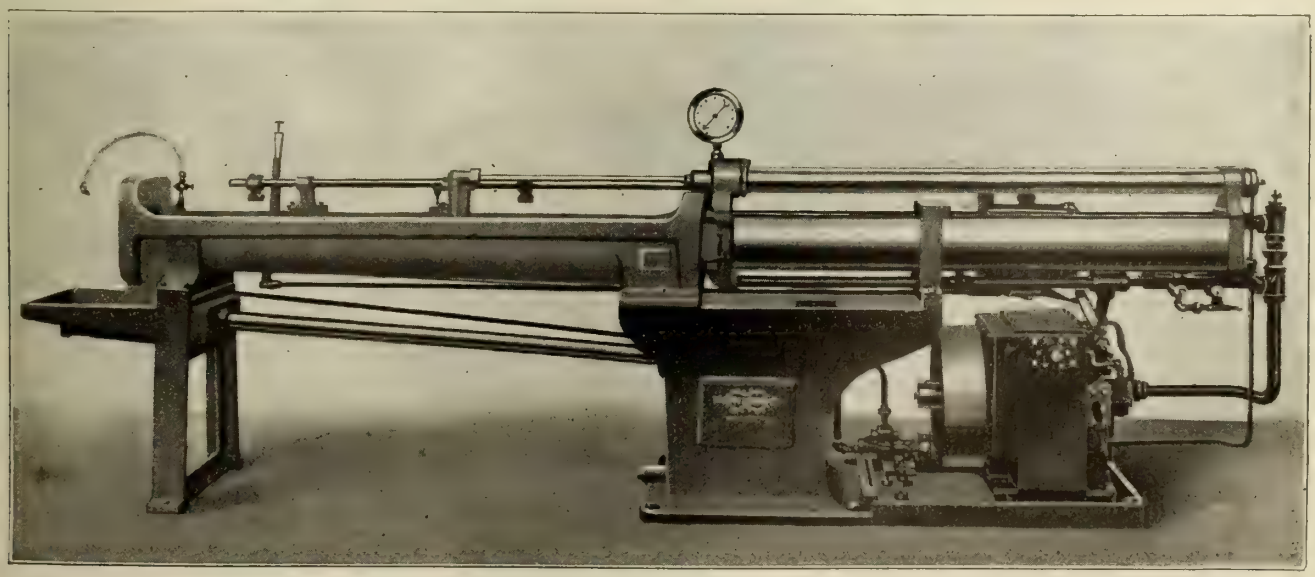
A variable-delivery pump, similar in design and operation to those used on oilgear variable-speed drives, delivers a perfectly steady flow of oil to a double-acting cylinder, whose piston rod is connected to a sliding head which operates on ways in a U-shaped trough of the usual design. The amount of oil delivered to the cylinder depends upon the length of the pump stroke and this length can be varied from zero to a maximum. As the speed of piston travel depends on the amount of oil pumped into the cylinder, this speed can be changed at will merely by changing the pump stroke. Right here it is important to note that it is primarily because of this method of controlling the speed, coupled with the even flow of oil delivered by this type of pump, that makes it possible to use high speeds. The cutting stroke is started without shock and the pull is steady.

There is practically no limit to the choice of speeds for either the cutting or return strokes within the limits of 48 inches and 360 inches per minute. Very slight variations are easily obtained. Exactly the right speeds may be selected for different materials and different broaches, higher speeds for light cutter bar work and slower speeds for heavier jobs. The speed of the return stroke is adjustable entirely independent of that selected for the cutting stroke. Automatic stops are provided; these can be set for any desired length of cutting stroke and this length will remain fixed. There is no overrunning and consequently no danger that the broach will be pulled beyond the reducing bushing and be caught on the reverse. Little effort is required to reverse the machine at either end of the stroke as there are no heavy clutches to shift. Simply pressing down on a small push button reverses the machine or the control may be set for automatic reversing. An emergency lever enables the operator to stop the machine instantly at any point of the stroke.

Quick-acting relief valves prevent the pulling apart or the buckling of a broach. These valves, one of which is placed on the cutting end and one on the return end, automatically relieve the pressure and stop the machine whenever it builds up to a predetermined point. In case a broach is caught during the cutting stroke, the relief valve, set for a pressure slightly greater than that necessary for the normal pull, will act and stop the machine before the machine or the broach can be damaged. Likewise, any excessive load on the return stroke will cause the relief valve on that end to act and stop the machine instantly.

These broaching machines are driven by vertical belts from line shafts or motors. When a motor is used, it may be mounted above the main cylinder on an adjustable support.

The principal specifications of these new machines are as follows: pulling capacity, 16,000 lb. (equivalent to that required by a 2-inch square broach designed according to standard practice); speed range for either cutting or return strokes, 48 to 360 in. per min.; stroke, 56 in.; diameter of hole in face plate, 5 in.; vertical adjustment of drawhead, 1⅝ in. above and 1⅝ in. below center; driving pulley, 600; motor size recommended, 10 h.p.; net weight, 2,900 lbs.; floor space required, 16 ft. long by 26 in. wide.



High Speed Hydraulic Broaching Machine.

AUTOMATIC WELDING MACHINE

An interesting type of automatic welding machine has just been developed and placed on the market. The torch is mounted at one end of a connecting rod that is moved by means of a crank at the opposite end. The path of the nozzle can be varied by altering the position of the pivoted guide, the welding flame having an elliptical movement when in operation. The entire machine may be given a motion at right-angle, to that imparted to the connecting rod. By manipulating the different adjustments the torch may be made to travel in a number of varied contours. The welding rod is fed automatically by gravity, as it passes through the centre of the torch and welding tip. The oscillating motion is very suitable for seam welding. When heavy pieces are being welded an additional torch precedes the welding torch for preheating purposes. The machine is arranged for two speeds, one by friction wheel and disc and the other by rheostat for motor control. This latter provides for speed variation when welding parts of varying thickness. These welders are made by the General Welding and Equipment Co., Boston, Mass.

TOOL GRINDING MACHINE

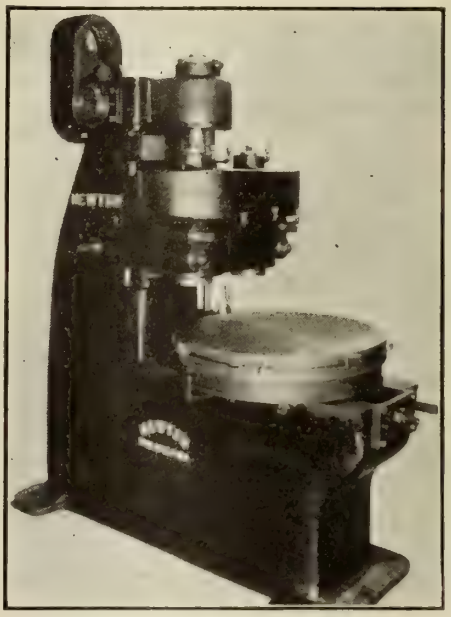
An imported machine especially designed for grinding lathe, planer, shaper and slotter tools, has recently made its appearance on the market. The machine is also supplied with attachments for grinding milling cutters and twist drills. It is claimed that high speed tools can be ground without developing cracks on the cutting faces or softening the edges. The operation provides for automatic traverse of the tools over the face of the wheel. A worm gearing and adjustable connecting rod beneath the machine provides the necessary reciprocating motion. The slide rest mechanism permits of motion either parallel or at right-angle to the wheel face. Automatic or hand feed may be used. Gauges are provided for setting to desired angle of inclination and to proper height for grinding. The grinding compound is contained in a tank at the base of the machine and is circulated by means of a Brown and Sharpe pump. The speeds are 2,000 r.p.m. for large wheels and 6,000 for small ones. An automatic stop prevents the wheels from overspeeding. The machine is made by Hotchkiss Co., Paris, France, and is marketed by J. B. Corrie and Co of London, Eng.

SOFT METAL MELTING FURNACE

A gas furnace which has a removable cast-iron pot with a capacity of 150 lbs. of metal has recently been placed on the market. The gas is delivered to the furnace through three bunsen burners and it is claimed that a temperature of 2,250 deg. F. can be developed with a consumption of 40 cu. ft. of gas per hour, and this heat maintained by the use of two burners. Shut off valves, pilot lights and regulators are fitted to each burner. Regulators may be adjusted to suit varying qualities and pressures of gas and it is stated that a solid jet of gas can be sent up the centre of the mixing tube with great pressure and without the use of a forced air blast or blower, producing a flame of high temperature. These furnaces are made by the Johnson Gas Appliance Co. of Cedar Rapids, Iowa.

CONTINUOUS MILLING MACHINE

A vertical machine especially designed for continuous operations on small parts has been placed on the market. The machine is equipped with a splash tub when using cutting lubricant. The illustration herewith shows the machine with the tub removed, in order to clearly show the controlling dogs used on the intermittent motion.



Continuous Milling Machine.

The table has two separate and distinct types of feed motion; the first for straight continuous milling, the other being intermittent feed and rapid traverse, in which the rapid traverse is at a ratio of 10 2/3 times the feed for limited quantities or where the surface to be machined is less in area than the casting itself. This table is of the solid top, arranged for bolting and dowelling the jigs; has two bearings, one being an annular bearing so that the table only overhangs the saddle ⅝ in., making any twisting or buckling impossible. The table is rotated by helical gear fully enclosed, and this gear, together with the table bearings, runs in oil. The pinion operating the table and helical gear is rotated by a large diameter worm and worm wheel, and with this combination of gearing all back lash is prevented. The feed motion is supplied with lever for disengagement and with safety clutch of the overrunning type to prevent breakage in the event of overloading or jamming the machine in any manner. Table feeds are variable through the use of pick-off change gears. Table saddle is adjustable on the base, providing ability to position the table in relation to the cutters. Spindles are of taper end construction with face keyway, Morse taper hole and draw-in bolt; are driven by hardened steel gears and supported between bearings fully enclosed to run in oil. The sleeve in which the spindle is confined provides an individual end adjustment for setting cutters of 2 in., with of course provision for clamping after it is located.

The motor is mounted on top of machine, driving through pick-off change gears to provide variation in spindle speeds. The various dimensions of machine parts are as follows:—Table, 30 in. dia.; maximum height of table top to underside of spindle faces, 12 in.; cutter capacity up to 10 in. Motor is of 7½ h. p. This machine is made by the Newton Machine Tool Works, Inc., Philadelphia, Pa.

INSIDE MICROMETER AND HEIGHT GAUGE

A low range inside micrometer having measuring facilities from 2 to 7 inches has been placed on the market. Additional rods may be provided to increase the range to 32 in. Ample provision is made on the barrel and thimble for wide graduations and comparatively large figures. By means of a small base block the device can be conveniently converted into a height gauge. The rod passes through the hardened base until it rests on the surface from which the measurement is to be taken. The rod is held in a vertical position and firmly in place by means of a quick-clamping knurled nut, easily operated with the fingers. The V-shaped groove in block provides for operation on cylindrical shafts for alignment purposes. These tools are made by the Reed Small Tool Works, Worcester, Mass.

MULTI-SPEED MOTORS

A line of multi-speed A. C. motors has recently been placed on the market. These machines are designed to supply speeds ranging from 600 to 1,800 r.p.m. Motors may be obtained for constant horsepower, constant torque or any required combination of both in two, three or four speeds, selected from 600, 720, 990, 1,200 and 1,800 r.p.m., either for circuits of 60 cycles or other frequencies and of either two or three phase. It is claimed that the speed control apparatus is suitable for both automatic and remote control. These motors are manufactured by the Mechanical Appliance Co. Milwaukee, Wis.

ANGLE PLATES

The Milliken Machine Co. of West Newton, Mass., has placed on the market a line of angle plates made in seven sizes and are planed on the outside surfaces and edges. They range in size from 3 x 3¾ x 3¾ in to 12 x 12 x 12 in. The intermediate sizes have one stiffening rib while the largest sizes are fitted with two ribs.

B. C. Wants To Compete

"WHY should the legislature have to guarantee bonds to the extent of four million dollars to establish the industry?" asks the Winnipeg Tribune with reference to the proposal to establish a fifteen-million-dollar steel corporation in British Columbia. The paper expresses the opinion that existing steel mills can turn out more steel than the world can use, except for special occasions, and claims that there is more urgent need for a satisfactory supply of domestic fuel. There is something in the contention from the point of view that there is more stability in well-balanced industrial development than in concentrating along lines which overstrain the possible market. In that event something must break or wait. However, it is evident that British Columbia feels itself isolated and dependent as a buyer of iron and steel, and their products, and that there is something that appeals in being in a position to compete. It is pointed out that government aid is conditional upon a full investigation as to the possible supply of raw materials, management and methods of financing and prospects of success. The Western market for agricultural implements and other products, the marine and mining industries, together with export possibilities, combine to make the proposition an attractive one to the British Columbians. The question they are undoubtedly investigating most seriously is, Will the possible market guarantee the success of such an industry at the present time?

Labor Wants More Compensation

DURING the recent labor convention in Montreal, certain extensions to the Workman's Compensation law were recommended. Every worker engaged in the building industry it was argued should come within the scope of the compensation law, and it was held, further, that the compensation should be increased from 66 2-3 per cent. to the full extent of the wage.

This latter proposal represents one side of the question. Judging from the statistics presented in the last annual report employers will hardly take kindly to further increases in that respect. It is unfortunate that a certain amount of prejudice has developed largely as the result of conditions following hard upon the war when much was heard of high wages for poor values, and when there were frequent complaints as to malingering. These abuses are disappearing as workmen recognize their personal and relative responsibilities and as unscrupulous medical advisers are being eliminated. Employers, however, will declare that there is such a thing as reasonable limits.

The extension of the Act in respect to the building industry immediately suggests difficulty of operation, even if changes were acceptable. Some very absurd problems could easily develop, and the operation of the general assessment system to work in with the requirements of the compensation laws might become quite an intricate piece of business. Yet, a great many accidents occur in connection with odd jobs where no person at present admits responsibility. It would seem advisable that there should be some regulation applying to such cases.

Ford Uses Strike Weapon

THERE is considerable speculation among business men as to what may or may not be in the background of Henry Ford's move to close his plant September 16. There is always more or less conversation when Ford does anything and it has always developed that what he proposes to do generally happens, with very little variation. Imagination weaves many fantastic stories around Ford and his plant, his motor car and its future. At the present time there are those who declare that the number of cars actually in stock will make it an easy matter to suspend operations for the time being, and that present labor troubles enable him to present a plausible excuse. Those who have had any business dealings with the flivver magnate, however, do not hesitate to credit him with sincerity in the present instance, and that his position is just so strong that he can deliver quite an impressive demonstration of the significance of a strike on the part of a manufacturer against coal profiteering. He is out to prove that it is a poor rule that has only one application, and if successful he will have done a real service to industry generally.

Safety Lessens Wastage

AT A RECENT safety congress, where methods and policies in the reduction of industrial accidents and fatalities were considered, one fact had particular prominence, namely, that a certain responsibility devolves not only upon the safety engineer, superviser or foreman, but upon the rank and file of employees themselves. Carelessness in organization and in instruction, it was shown, made for great wastage of life and limb, time and money. On the other hand it is shown that when every precaution is observed, the results proved well worth while and were such as to enlist the co-operation of those concerned. It was easily demonstrated that there was lessened wastage through accidents and compensation costs and that there was not only increased production but lessened costs of production.

It is another instance where employees ignoring old-time practices and prejudices, have developed considerable benefit for themselves by working with their employers rather than merely for them or preferring to recognize no relative responsibility.

Steel Market Advances all Along the Line

Bars, Boiler Tubes, Skelp Move Upward—Deliveries Prove Serious Problem—Bookings Fairly Good for Structural and Motor Car Business—Montreal Reports Demand for Heavy Scrap Following Scarcity of Pig Iron—Some Remarkable Advances Since June

RAILWAY SHOPS NEED NEW EQUIPMENT

ADVANCES all along the line in iron and steel are the order of the day. This is the result, it is declared, of wage rate increases and the general upward trend in all factors having to do with production. Deliveries are the problem. It is declared that, at this distance from central markets, there can be no conception as to the difficulties that confront shippers. Much business is booked for Toronto for the structural and motor car business alone, and while there are instances of good work in laying down the goods here, these are regarded as exceptional. What the situation must be at points whence many sections of the continent have to be served, it is hard to imagine.

Notable examples of increases during the week are skelp, used in making pipe, which advances $8 per ton, while boiler tubes score a boost of 20 per cent. Reports from Pittsburgh show reductions of three points of discounts on lap welded and seamless boiler tubes. This amounts to $6 the ton. Makers of charcoal iron boiler tubes have issued a new card, on which discounts on all sizes have been reduced seven points. An increase of $14 per ton in boiler tubes is an item on which advances have been expected for some time. Announcement of an advance of ten cents on steel and iron bars has been made. At $3.35, this represents an advance of 60 cents since June. This is fairly representative of the movement in the market at the present time. Still the demand continues to show encouraging strength.

Montreal reports that the close of August showed an improvement and that the month on the whole measures up favorably with those preceding. Here too, it is noted that deliveries are a handicap. Imports from British mills are increasing. Practically all of the galvanized sheets and much of the blue annealed are coming from that source. Some Scotch pig iron is available in the Montreal market, but the situation in this department is responsible for a demand for heavy scrap.

Toronto

Sept. 6.

WITH pig iron ten dollars a ton higher than the quotations of eight weeks ago iron and steel bars, forty cents per hundred pounds higher and showing a boost this week of 10 cents; skelp $8 per ton higher, while wrought pipe has advanced $4 and likely to go the full distance indicated by raw material; boiler tubes higher by 20 per cent.; sheets of all kinds showing marked advances and many items in the metal list tending upward, buyers must feel that all predictions and all warnings as to a disturbed market have just about been fulfilled.

The pig iron situation shows a more or less helpless response to scarcity of coal, difficulties of deliveries and upward moving wage lists. Supplies of pig on hand have been pretty well covered by contract, and he is a fortunate buyer who landed on the ground floor when the price was around $28 a ton. With Hamilton and Port Colborne furnaces out, and Algoma with limited capacity, furnaces coming into the market for spot or future are going to find a difference. It would not be surprising to find eastern and Scotch pig invading the Western Ontario market, for there is some problem even about deliveries from Buffalo. Given the makings on one hand there is the question of transportation; given transportation, there is again the question of price, and over against that there is the danger of conservative buying and curtailment of operations due to coal scarcity. The situation, however, is not without hope. As one manufacturer puts it, "Everybody seems ready to go, the crop outlook is splendid and the general feeling is that the time is at hand when industry should hit a regular stride. We hope that time is not far off."

Algoma, No. 1, car lots on tracks, nominal quotation	40 80	....
Summerlee, 5-ton lots, warehouse	38 50	33 50
Summerlee, 30-ton lots, dock	33 50	....
Carron, 30 ton lots, dock	35 00	....

The 20 per cent. wage increase by the U. S. Steel Corporation has become general among the large steel corporations but as yet no general price advance has occurred. The increase of 25 per cent. some weeks ago is sufficient for the moment, but the last quarter may see revisions upwards.

One change, long predicted, has at last arrived—an advance of 20 per cent. is announced on boiler tubes. There is said to be scarcity in stocks on Toronto market in this department and some variance in quotations in different quarters. The advance should at least make for stability.

Bars and sheets, which have for weeks been most active on the list, still reflect an active demand. The advance of ten cents on bars is another step nearer the maximum of $3.40 set by those who claim that market conditions warrant higher prices. However, more conservative sellers have adhered to slightly lower levels. With steel bars quoted at $2.70, Chicago warehouse, the spread as between that point is estimated at from 65 to 70 cents. The sheet market is active but inclined to be more spasmodic than one month ago, indicating, it is said, that fair stocks have accumulated in anticipation of the present situation.

Large importers say the demand still holds for structural shapes and bars, and that the automobile industry is also taking fairly large quantities of material. Deliveries however, are not improving. Following are selections from local quotations:

Iron bars	3 35	3 40
Steel bars	3 35	3 40
Reinforcing bars	3 35	3 40
Steel hoops		4 50
Tire Steel		3 40
Spring steel	7 00	14 00
Band steel, No. 10 gauge and 3-16 in base		3 75
Small shapes		3 40
Sheets, black, No. 28		5 00
Sheets, blue ann., No. 10		4 05
Canada plates, dull, 52 sheets		5 75
Caanda plates, all bright		6 00
Galvanized Sheets, No. 28		6 35

Scrap metals remain quite inactive. No price changes have occurred that might be said to indicate a decided movement. Mills evidently have no desire to load up to any extent with cast iron scrap and the price has shaded 50 cents a ton, but this has little or no significance as to the general market. Current prices follow:

Copper, light, per 100 lbs.	9 00
Copper, crucible	11 50
Copper, heavy	11 25
Copper Wire	11 25
No. 1 compositon	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 25
Light brass	4 50
Medium brass	6 00
Scrap zinc	3 60
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton.	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine cast iron	20 00
Pipe, wrought	7 00

Non-ferrous metals have not been conspicuous features of the market for some weeks and there is very little variation in prices. Quotations of from $17.50 to $17.75 for copper represent a firm level. Tin, spelter, lead and antimony are fairly strong, and a little easing is apparent in antimony at $21. Quotations around which business is being done, follow:

Lake copper	17 75
Electrolytic copper	17 50
Castings, copper	17 00
Tin	37 00
Spelter	8 00
Lead	8 00
Antimony	8 50
Aluminum	21 00

Machine tool business, during the latter part of August showed no improvement. "We are selling some tools," seems to be the general report. A machine here and there is being sold, with an occasional sale that is declared to be worth while—this is characteristic of the market. Woodworking machinery is showing nice business, and supply departments show fairly good records. Displays at the Toronto Exhibition are attracting considerable attention and a few sales are reported. Railway shops appear to be promising ground for machinery salesmanship. A representative returning from an inspection of important shops recently reported, "They need machinery, but the time doesn't seem to have arrived for a final o.k. The government is cautious in its buying for railways and the C. P. R. have apparently adopted a similar policy. One of these days they will release some good business."

In the malleable fitting list it is predicted that dealers' discounts may have a slight reduction. At present it stands at seventy and five. The five may disappear.

Quick Changes Feature the Market

No sooner is an advance announced of $4 a ton in the pipe market than skelp, used in large quantities, is advanced to $42 a ton, a boost of $8. Deliveries on this material are difficult. Further advances in the finished article are predicted.

A slight reduction has been recorded in turpentine, the price per gallon in barrels being $1.65. Raw linseed oil is posted at $1.01 per gallon, barrel lots.

Pittsburg

Sept. 6.

THE upward swing in pig iron and steel prices continues, and with greater speed. There is the double influence of material being scarce and of sellers, as indicated in the report of a week ago, having concluded that there is no use trying to hold prices down, in the interest of stability, for the astonishing victory of the United Mine Workers and other labor matters, have forced inflation into the situation. Th individual now feels that a reaction is inevitable some time, followed by a serious depression, and that meanwhile the only reasonable course is to secure as high prices as possible. As to when the break will come there is a wide range of predictions, from say two or three months up to a year.

Of particular interest in this connection is the appearance that the United States Steel Corporation is not making its usual effort to hold prices down. The corporation does not originate price advances, but shows little hesitancy in following advances, once made, by the independents. In 1920, and in the fore part of 1917, the corporation was very conspicuous in holding its prices at levels far below what was obtainable in the open market.

Coal and Coke Strikes.—Following the "Cleveland settlement" by which about 15 per cent. of the bituminous coal capacity formerly union signed the 1920-22 wage scale of the United Mine Workers for a period up to April 1, next, various individual operators or districts held out for a time, there being a drift towards signing. The Pittsburgh district held out the longest. On one day, after the Pittsburgh Coal Company had withdrawn, the Pittsburgh Coal Producers' Association decided to sign, and the next day the Pittsburgh Coal Company also signed, whereby the regular union bituminous coal strike was practically over, with a tremendous victory for the miners.

As to the strikes in the Connellsville region, which the trade has been calling "nonunion" since the region has been nonunion for over 30 years, but which the strikers considered union as they had suddenly joined the United Mine Workers by paying $1 or $2 each initiation fee, the posting notices, August 22 and 23, restoring the scale of September 1, 1920, the record high scale of the region, did not stop the strikes instantly. Various meetings were held at which resolutions were passed to hold out for union recognition. Men drifted back to work in somewhat larger numbers than formerly. Day by day the trade watched the situation, but considered the strikes still in force, to an extent. September 1 came an almost comical denouement, for on that day car shortages were serious. There remained many strikers but the available jobs were filled. Actual shipments of coal and coke have simply increased somewhat more. They have been increasing more or less since last May. They are not large now, in proportion to requirements, and since September 1 the market has been stiffening. Connellsville steam coal is $4.75 to $5.25, furnace coke $11 to $12 and foundry coke $13 to $13.50, all per net ton f. o. b.

The Shenango Furnace Company picked up enough odd lots of coke, at $10 to $11, to enable it to resume at one small furnace, but as this is on Bessemer iron to be delivered molten on a long term contract with an ingot mold foundry, it does not affect the merchant iron situation. Merchant furnaces in general cannot pick up enough coke with which to resume, irrespective of prices.

The pig iron market remains one of spot or prompt shipment, practically out of stock. Bessemer is up, on small sales, $2 a ton to $34, valley. It is said basic could not be had under $30, valley, but there is no likelihood any could be had at that figure. As to foundry iron the last valley foundry was sold some time ago and consumers have had to go farther afield. A couple of days ago a transaction occurred disclosing the situation plainly. A consumer in Pittsburgh wanted about 400 tons of foundry iron, and had to buy it in Buffalo, paying $34 at furnace. Adding freight to Pittsburgh and deducting freight from the valleys makes a valley equivalent of approximately $35 50, or $2.50 above the valley market previously quoted. Last March the valley market was $19.

Steel Production.—While coal production is increasing it can hardly increase to anything like the level of requirements, on account of transportation limitations, and steel producers and consumers are not given sufficient preference in the railroad distribution to improve their supplies much, while the few remaining stocks of coal have been playing out. It is a question whether the rate of steel production will be materially higher 30 days hence than it has been in the past week or two, when the rate of steel mill operation in general has been between 50 and 55 per cent., or say a little over 25,000,000 tons of ingots a year. The maximum this year was between 70 and 75 per cent., reached late in June, with an ingot rate of about 37,000,000 tons a year. It is doubtful whether such a rate will again be attained at any time this year.

Small lots of sheet bars have gone at $40, following a recent sale of 2,000 tons at $38. In the first quarter of this year the market was $29. Still higher prices are predicted. One mill is "asking" $45 for sheet bars. Billets and slabs show no movement and can be quoted nominally at the same level as sheet bars. Wire rods have sold at $43 as a special accommodation, the usual asking price being $45.

The minimum on bars, shapes and plates went up from 1.80c about ten days ago to 1.90c on bars and 2.00c on shapes and plates, but it is difficult to buy at these figures, and then the delivery would be far in the future. The regular going market on all three products is really 2.25c, for ordinary deliveries, while plates for shipment in two or three weeks are bringing 2.50c quite readily.

Since the American Sheet and Tin Plate Company's advance to a basis of 3.35c for common black sheets, independents generally have gone to 3.50c, with prospects of their going higher, as the leading interest has not been selling in the open market, merely allocating tonnages to regular customers.

Recently independent wire mills advanced plain wire $2 a ton to 2.35c and nails 20 cents a keg to $3.60. The leading interest is now selling at these prices but has not made its usual formal announcement of a price change.

Hoops, bands and hot rolled strips are now firm at 2.75c.

Manufactured steel products show a sharp advancing tendency, due to the double influence of the hot rolled raw material being higher in price and of deliveries being very poor. Spikes are up $5 a ton to 2.75c for standard railroad spikes and 3.25c for small spikes and boat and barge spikes. Cold finished steel bars have advanced from 2 25c to 2.50c. On cold rolled strips 4.00c has disappeared, 4.25c now being the minimum. Rivets and various other commodities are predicted to advance shor ly.

Montreal

Sept. 6.

ALTHOUGH reports from various quarters during the last two weeks of August led one to believe, that when the total figures for the month were known, that they would be lower than those of July, quite a number of jobbers state that August business compares very favorably with those of previous months.

Steel deliveries are gradually getting more distant, and stocks are getting thinned out slowly. Prices have not advanced during the week, and material to cover all orders has been forthcoming.

Pig iron is the feature on the local market. It is daily getting harder to obtain and quotations are going up. Machine tools are quiet and there is not much movement in non-ferrous metals. The scrap metal market is a little more active and some quotations are advancing.

Iron and Steel.—Outside the fact that supplies are getting more difficult to obtain, conditions have remained much the same as last week. Merchant bars and structural steel are moving somewhat slower than during the past few weeks. Plates have been very quiet. Sheets continue to be very active, but the demand is slackening off somewhat, as the fall demand has not made itself apparent as yet. Small steel products are moving well. Practically all the galvanized sheets and some of the blue annealed sheets are coming in from British mills. More or less steel is being imported from the United States, and at the same time the local mills are doing a nice business. Quotations remain the same as last week. The mills charge $2.60 base to the large consumers and $2.70 base to the jobbers and contractors. With the increased wage to steel workers operative as from Sept. 1st, and the generally unsettled conditions, there is no doubt but that higher prices for steel are to be expected. The following are the local quotations.

Iron bars, base	3 15 to	3 25
Steel bars, base	3 15 to	3 25
Reinforcing bars, base	3 15 to	3 25
Steel hoops		4 25
Tire steel	3 25 to	3 40
Spring steel		7 00
Band steel, No. 10 gauge and 3-16" base	3 65	3 75
Small shapes		3 40
Sheets, black, No. 28		4 40
Sheets, blue ann., No. 10		4 05
Canada plates, dull, 52 sheets		5 50
Canada Plates, all bright		7 00
Galvanized Sheets, No. 28		6 50

Pig Iron.—Supplies of pig iron are very scarce. The Canadian furnaces are not attempting to get any new business as they are short of coal. Their present supplies are not more than sufficient to carry them through orders already booked. Summerlee iron is being offered in small lots, and it is expected that Carron will be on the market any day. The nominal quotation of Canadian furnaces is $40.80. Buffalo quotations on track Buffalo for delivery in Ontario are $36.00 plus freight and duty. Algoma Steel Corp. have ten thousand tons in their yards at the Sault, but it is all contracted for, and will be shipped within six weeks. Local quotations are as follows:

Algoma, No. 1, car lots on tracks, nominal quotation	40 80	.....
Summerlee, 5-ton lots, warehouse	38 50	38 50
Summerlee, 30-ton lots, dock	33 50	.....
Carron, 30-ton lots dock	35 00	.....

Machine Tools and Supplies.—The machine tool markets continue to be very quiet, but few sales having been made for several months. There are a few more inquiries for small iron working tools coming in lately. It is hoped that these are the forerunners of better business. Woodworking tools are moving somewhat better, although this movement is not brisk.

The supply business is improving slightly, having to a certain extent recovered from the small falling off noted late in August. Prices remain unchanged.

Non-Ferrous Metals.—Trading in non-ferrous metals has been rather quiet during the week. Reports from London markets indicate a tendency toward stiffening quotations. To a certain extent this is offset by unsettled business conditions in Europe. Locally the outlook possesses possibilities that might react for an improvement. Local quotations are as follows:

Lake Copper	17 75
Electrolytic Copper	17 50
Castings, Copper	17 25
Tin	35 50
Lead	7 00
Spelter	8 75
Antimony	6 25
Aluminum	22 00

Scrap Metals.—Coincident with the scarcity of pig iron, a demand for heavy scrap has appeared locally.

There have been somewhat better prices ruling and the demand in many lines is better.

Prevailing quotations are as follows:

Copper, light per 100 lbs.	9 00
Copper, crucible	11 50
Copper, heavy	11 25
Copper Wire	11 25
No. 1 composition	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 25
Light brass	4 50
Medium brass	6 00
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine cast iron	20 00
Pipe, wrought	7 00

SALES TAX ON USED MACHINES

Dealers in machine tools declare that some misunderstanding exists as to the application of the sales tax, where an old machine is turned in as part payment on a transaction. The department of Customs and Excise has ruled that when a manufacturer or wholesaler in selling goods takes back an old machine in part payment and makes an allowance for same off in the selling price, the sales tax applies on the selling price without any deduction for the allowance. Thus if the selling price of the goods is $1,000, and the purchaser turns in an old machine or, in fact, any goods for which an allowance is made, say for example $200, sales tax applies nevertheless on the selling price of $1,000. Where a manufacturer sells and delivers from his factory a second hand machine the department of Customs and Excise regards him as a wholesaler in respect of such sale and he is required to charge and account to the Government for a sales tax of 2¼ per cent. thereon. For example, a manufacturer may take into his factory warehouse an old machine in part payment for a new machine, and when selling the second hand machine, so accepted as part payment, the manufacturer is regarded as a wholesaler and the sale is subject to a tax of 2¼ per cent. Note—Where a manufacturer sells equipment discarded from his factory such sale is not regarded as taxable under the Act. This is by reason of the fact that the manufacturer when buying machinery and equipment for his own plant is regarded as a consumer and such sales do not come within the meaning of the Act.

Scrap—The Department of Customs and Excise has ruled that scrap sold by a concern which is a consumer thereof when the goods are purchased, is not subject to sales tax when sold by such concern. This is to say, when a manufacturer is selling scrap or waste, being the deteriorated material of his scrap equipment or otherwise, but in respect of which he was rated as a consumer at the time of his purchase, the sale by him in the condition of scrap or waste, is not subject to payment of sales tax.

MACHINE TOOL EXHIBIT

A machine tool exhibit that will be of special interest to shop-superintendents, purchasing agents, master mechanics and the general public will be held in the Mason Laboratories, New Haven, Conn., on Sept. 21, 22 and 23 under the auspices of Yale University and the Connecticut section of the American Society of Mechanical Engineers. The exhibition should prove of material value to the manufacturer for it will really be the first time they have ever been able to show their goods on a large scale. There will be talks each day on the most important features of the exhibit and the talks will in most every instance be illustrated with motion pictures.

Sawmills for Poland.—The enormous forests of Bialowieza in Poland, containing thousands of acres of uncut timber, are attracting the attention of British concerns, who are negotiating for leases. United States concerns, that are interested, have also sent an agent to Warsaw, who in company with H. A. Smith, trade advisor to the American legation at Warsaw, is now on a tour of inspection of the forest lands.

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

PIG IRON

Toronto price:—

There's Only One Way to Buy Machinery
Usually, when you buy machinery, you do so because you need increased daily production. You cannot expect this with any degree of confidence unless the machinery you buy is backed by the guarantee of a reputable concern—an unrestricted guarantee, based solely upon absolute satisfaction of the buyer. This is exactly what the Williams' Guarantee covers—it is a guarantee that protects the purchaser in every way.
Our regular monthly Machinery List is full of bargains. Shall we put your name on our mailing list?

HEAVY LABOR IN DEMAND

(Continued from page 40)

nine increases April 15 to May 15; twenty-three reduction and twenty-six increases May 15 to June 15; twenty-five reductions and twenty-one increases June 15 to July 15, and seven reductions and eight increases, July 15 to August 15.

The hourly wage of all wage earners ranged from 24.3 cents in July, 1914, up to 62.1 cents in September, 1920; then down to 48.2 cents in January this year. Hourly earnings of all male skilled labor, starting at 28 cents, advanced to 70 cents and has dropped to 55.5 cents. The hourly wage of all male common labor, starting at 20.7 cents, advanced to 54.6 cents, then fell to 39.8 cents. The hourly wage of women, beginning in July, 1914 at 15.6 cents, advanced to 41.7 cents, and has now fallen to 34.7 cents.

Weekly earnings are shown for the same classes in the same way. Thus in July, 1914, the composite rate for all wage earners was $12.36. It rose to $29.69 in July, 1920. In January this year it was $22.27. The pre-war figure for all male skilled labor was $14.19 the high figure $33.54; the figure in January, $25.66. For male unskilled labor the figures were $10.89, $27.14 and $18.95. For women the figures are $7.82, $18.79 and $15.76.

PRODUCTION MILLING

(Continued from page 41)

used for roughing out the fork while the two shown on the near spindle finish the space to the desired demension. It will be seen that this fixture varies somewhat from that shown in Fig. 1, as the one first described was of the direct clamping type while the one in Fig. 2 has a three point bearing, the front edge resting on two of the yokes and the rear of the clamp bearing on a raised rib on the inner diameter. The production on these parts is at the rate of 216 per hour.

The feed for both of these jobs is continuous at one constant speed, the parts being so close together as to allow the cutters to be engaged practically all the time. The machine however, is designed with two table speeds, the one just mentioned for cutting and the other for traversing space between the work, where the cutters are not engaged. The ratio of these two speeds are as 10 2-3 to 1. The change from one to the other is automatic, the shift being made by means of a lever which is operated by adjustable stops located in a t-e-slot around the outer edge of the milling machine table.

NOVEL COAL-HANDLING PLANT

Engineering visitors to British ports must have been struck with the great improvement made during recent years in the mechanical appliances for loading coal. An installation recently completed at a British harbor includes many interesting features introduced specially to ensure that the coal will not be broken up when being lowered into the ship's hold. The wagons are drawn up an incline shoot to an ingenious anti-breakage box which lowers it gently down to the ship's hold. This anti-breakage box consists of a vertical tube inside of which are steel plate trays fitted to a pair of endless cha ns. The coal from the shoot slides on to one tray, which then falls by gravity and brings another tray opposite to the end of the shoot to receive its charge. Each tray-load as it reaches the bottom of the tube releases its contents with the least possible shaking up and then rises up the other side of the tube to take its place once more opposite the shoot. The operations are so arranged that by the time one truck load has reached the hold another full truck is ready to despatch its load down the shoot. The work is therefore continuous and is carried out at the rate of over five hundred tons per hour. All the plant is electrically driven; and, in continuous use for about six months, it has given every satisfaction.

News From the Industrial Field

Babcock & Wilcox, Ltd., Montreal, have been awarded the $31,408 contract for boilers for hospital, costing $2,500,000 in Ottawa.

Anglin-Norcross Co., Toronto, have been awarded the general contract for erection of collegiate and technical school in Kitchener. Sarnia Bridge Co. have the structural steel contract.

Addition to the Kingston penitentiary, costing $500,000, is proposed by Dominion Government, Department of Public Works.

Goldie and McCulloch Co., Galt, have been awarded the contract for installation of a horizontal water tube boiler in Riverdale Technical School, Toronto.

National Castings, Limited, Belleville, are installing a Pittsburgh electric furnace and making other additions to building and plant. New core ovens are being installed.

Warkworth, Ont., proposes to acquire a supply of electric power by building a transformer station at Bradley's corners, three miles from the village and enter into an agreement with privately owned plant.

Moncton, N. B.—On August 29th Humphrey's mill dam near this city was washed away, together with forty feet of the new highway bridge. Recent heavy rains caused the freshet of water.

Waterous Engine Works, Brantford, are operating from 75 to 80 per cent. with overtime in some departments. Considerable pulp mill equipment is in progress.

Montreal.—The Hon. J. A. Stewart, K. C., M. P., ex-Minister of Railways, who has been confined to the Royal Victoria Hospital here for the past few weeks, suffered a slight relapse, and his condition is considered serious.

It is estimated that the settlements now being worked out in connection with the coal strike will cost the public $300,000,000 more than last year for its 1922 fuel bill. The public will also have to pay more for manufactured articles on account of higher coal costs.

No further surcharge is now to be collected on international business, either freight or passenger, according to an announcement by the Railway Commission. The rate of exchange on freight from Sept. 1 to Sept. 14 inclusive is 1-32 of one per cent.

Hamilton, Ont.—To date this year thirteen new industries have located in Hamilton and prospects are stated to be even brighter for the future. Last year Hamilton saw the establishment of twenty-four additional plants within its confines.

There is considerable activity about the plant at Welland formerly occupied by Electric Steel and Metals. It is being converted for the production of manganese and other high class steels, heavy castings and mining equipment. Electric furnace capacity is being increased.

That the Port Arthur district is undermined with coal is the opinion expressed by Jules Cross, a mining engineer. He reports frequent outcroppings of anthroxolite which burns to a slight ash and throws out an intense heat.

As indicating the extent to which surplus war equipment accumulated during the war is still moving, two lots were allocated by the Salvage Board in Chicago recently, one for 767 single purpose machines and countershafts weighing 1,000 gross tons at $18.10 per gross ton, and 141 special purpose countershafts with hangers at $1.50 each.

There will be plenty of coal for domestic purposes in Alberta, Saskatchewan and Manitoba this winter if railways co-operate in transportation, discloses a report from Calgary. There is every prospect of increased production of Alberta coal this winter and Saskatchewan mines are also operating.

Welland, Ont.—An order for a standard 3-ton capacity electric steel furnace, with transformer and switchboard complete, has been secured by the Volta Manufacturing Company, of Welland, from the Hopetown Steel Works, Bathgate, Scotland.

Vancouver, B. C.—The Ketchikan Power Company has contracted for 2,000,000 feet of spruce lumber to be shipped to Australia, according to announcement made by Eldon Daly, manager of the mill. The shipment will be ready early in August, the mill now being busy working on it.

Grande Prairie, Alberta.—Some samples of iron ore brought in from the vicinity of Hudson's Hope have been assayed and found to be 60 per cent. iron. The deposit from which the samples were taken is exposed over an area of 700 feet wide by three miles long, with indications of immense covered area.

Montreal.—In order to handle with despatch the increased flow of grain that is expected through Montreal in the near future, the Harbor Commissioners have arranged to work the port grain elevators night and day hereafter, and also to place in commission lake carriers to the waiting ocean vessels. Figures supplied by the Grain Clearance Board show that from the opening of navigation to the evening of August 9, a total of 62,378,638 bushels were shipped, compared with 58,946,969 bushels for the same period last year.

Montreal.—Reports from Quebec Legislature state that it has been decided to maintain for the coming year, the reduced stumpage duties which were put into effect last year. This was done so that lumber companies may be encouraged to employ as many men as possible during the coming winter. The action will result in a smaller government revenue, but is considered to be advantageous to the province at large.

New Westminster, B. C.—The Westminster Paper Company has been incorporated with a capital of $250,000, to manufacture tissue paper for fruit wrappers and similar purposes. Pulp will be secured from the plants already operating in British Columbia and work has commenced on the company's plant here, machinery having been ordered.

Fredericton, N. B.—All indications point to a remarkable improvement in the lumber industry. Some of the leading mills are increasing their output fifty per cent. over last year, and others are preparing to increase their cut. Several operators who have not been working for a number of years will resume this winter.

Exports from New Brunswick to the United States are practically double now what they were this time last year, largely as a result of the revival of the lumber trade with the New York and Boston markets. Of the total declared exports to the United States from here during the past quarter ending June of $751,245, about $650,000 was under the heading of "wood and manufactures of."

Returning from the Walkerville territory, a Toronto machinery dealer states that developments are proceeding slowly in connection with the proposed extension of the Ford plant, that operations in the present plant have slowed up considerably and that some of the Walkerville plants depending upon motor car activity reflect between-season recession.

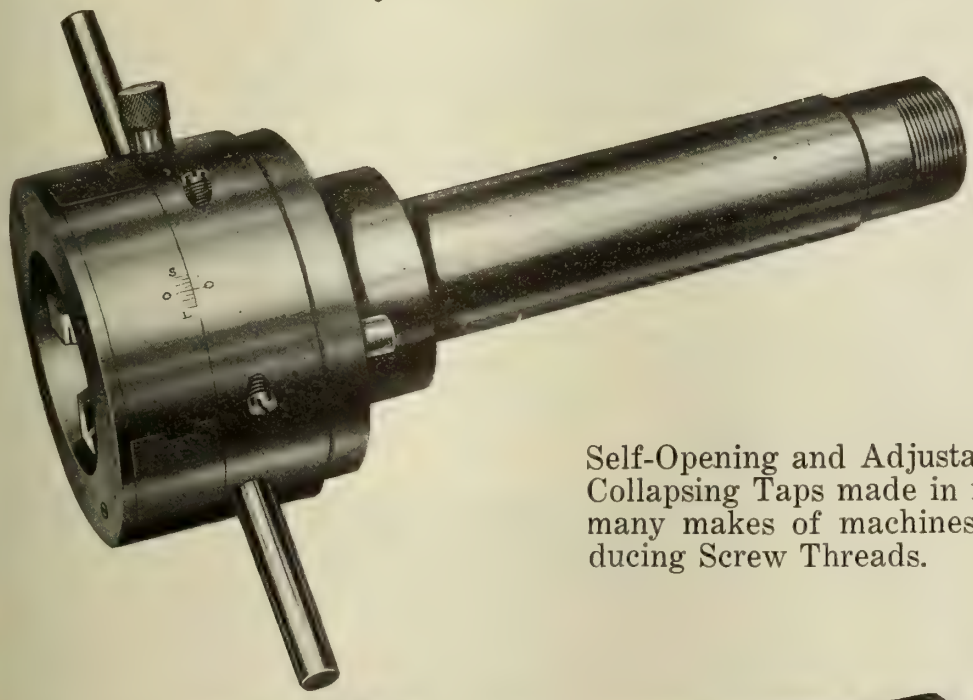
Discussing present-day wage rates, a Hamilton firm writes Canadian Machinery as follows:—"The fancy rates that adhered a year or so ago are now a thing of the past, and it is not necessary to pay men worth 25c per hour, 75c. The law of supply and demand is again asserting itself, and you can get a better run for your money to-day. There is no standard scale we know of in this territory, and the majority of the manufacturers are paying their men according to their earning power. The average machinist can be secured at a rate ranging from 40c to 55c per hour; select men are paid a little more; moulders, 47½c to 62c; laborers 30c to 35c."

GEOMETRICS

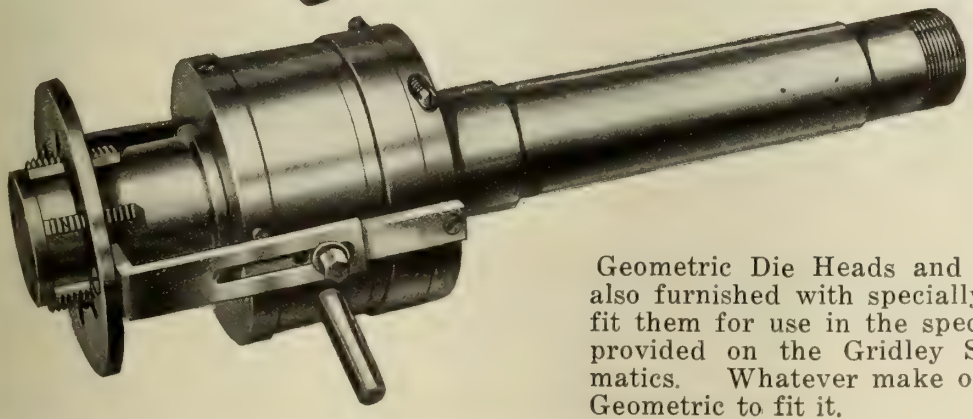
For Cutting Screw Threads

GEO MET RIC

Right on the Lead



Self-Opening and Adjustable Die Heads and Collapsing Taps made in many styles for the many makes of machines employed in producing Screw Threads.



Geometric Die Heads and Collapsing Taps are also furnished with specially threaded shanks to fit them for use in the special threading fixture provided on the Gridley Single Spindle Automatics. Whatever make of machine, there is a Geometric to fit it.

THE GEOMETRIC TOOL COMPANY

NEW HAVEN **CONNECTICUT**

Canadian Agents:

Williams & Wilson, Ltd., Montreal. A. R. Williams Machinery Co., Toronto, St. John, N. B., Halifax, N.S. Vancouver, B.C.

Toronto.—Contract for the construction of new buildings at Leaside, to cost approximately $1,000,000, has been awarded by the Durant Motors, of Canada, Limited. The new plant will have a floor space of 500,000 square feet and will be used exclusively for the manufacture of the Star car. Production for 1923 calls for 18,000 cars, 10,000 for domestic trade and 8,000 for export.

Toronto.—The three paper mills of the Spanish River Pulp and Paper Co. at Soo, Espanola and Sturgeon Falls, are operating 24 hours daily in order to keep up with the demand for paper. Usually at this time of the year they have been able to stock a certain amount of their production for winter supply but so far this year their entire production has been shipped out.

Petrolia, Ont.—Operations will be commenced, it is reported, this season in the construction of the Peninsula Sugar Company's plant here, at a cost of approximately $800,000. Machinery of special design, electrically driven, will be installed, and it is expected that the plant will be in operation by September. The refinery will have a capacity for slicing 600 tons of beets every twenty-four hours.

Ottawa.—The city of Ottawa has practically decided to use oil as a fuel for heating the schools of the city. It is considered to be more economical when all points are looked at. The matter has been brought to a head by the request of a local dealer to be released from his contract which called for him to supply the needs of the schools. It is believed that the matter will be finally disposed of on September 7th.

Montreal.—On August 31st the members of the Montreal Publicity Association held their regular luncheon on board the new C. P. S. Ltd. liner "Montclare." The "Montclare" was in Montreal on her maiden voyage. Over one hundred and fifty attended the luncheon. W. P. Ballantyne, general C. P. S. passenger agent was the host, representing the C. P. R. Captain R. Latta, commander of the "Montclare," and C. W. Stokes, general C. P. R. publicity agent, also officially welcomed the guests.

Efforts to secure uniformity in the matter of registration of trade marks and patents throughout the British Empire are progressing. A conference was held this summer in London and it was discovered that no system could be effective until there was uniformity in patent laws. In the meantime a loose scheme of co-operation between the various patent offices has been agreed upon. Of course, it must receive the sanction of the various governments concerned as the members of the conference could not bind their respective countries. Plainly there would be many advantages in uniformity in the matter of patents and trade marks throughout the territories under the British flag, but the impression left by the report is that many obstacles have to be overcome before it can be achieved.

Ninety per cent. of the 380,000,000 sacks of portland cement shipped in this country last year were delivered to the consumer in cotton sacks, each sack containing 94 pounds of cement. To meet this demand it is necessary for cement mills to keep large stocks of sacks in reserve. At the present time there are approximately 200,000,000 cotton sacks, either in sack storage houses at the mills, or in customers' hands. If the cement industry were called on to replace all of these sacks at once it would require over 200,000 bales of cotton to make the necessary cloth. Thirty million new sacks must be provided annually.

That business in Australia is fairly good but that after-war conditions have had the same effect there upon industry generally as in Canada, was the observation of S. B. Chadsey, manager Brantford plant, Massey-Harris Co., who with J. N. Shenstone, vice-president Massey-Harris Co., returned recently from Australia. The Brantford plant will close for stock-taking Sept. 9 for ten days. The staff will thereafter be increased according as market conditions and deliveries warrant. A one-storey solid brick addition to the plant with 7,000 square feet of floor space, is being built by Schultz Bros., Brantford.

Montreal.—Grain shipments through Lachine Canal in August totaled 12,200,329 bushels, which is an increase of 1,561,420, bushels over that of August, 1921. The principal increase was in wheat, a total of 9,087,621 bushels passed down this year as against 6,662,593 bushels last year in August. Oats, barley, and flaxseed shipments also increased, while corn and rye showed a decrease. No flour passed down in August 1921, while last month 31,500 sacks and 500 barrels were handled. Coal shipments in the canal were nil for the month, while last year a considerable quantity was handled.

The Imperial Radiator Company, Limited, an organization formed by the bondholders of Steel and Radiation, Limited, Toronto, have taken over the assets of the latter company, including plants and properties in St. Catharines and Toronto, for $400,000. The Toronto property is situated on St. Helen's and Dora Avenues, while that in St. Catharines is located on the N. St. C. and T. electric line to Merritton and adjacent to the present Welland Canal. Steel and Radiation, Ltd., has been in the hands of a receiver for some months, but has been running since the first of the year. It will have improved financial standing under the new order of things and attention will be confined entirely to the production of radiators and heating boilers. It is proposed to concentrate the manufacturing and head office in St. Catharines, retaining sales offices in Toronto. J. E. McAllister, Toronto, is president and E. T. Wingate, general manager in the new organization.

Anthracite operators announce that on resumption of mining prices of coal at the mines will not be advanced though bids of $12 a ton or $4 more than list prices are being made. With lower freight rates they declare there will be no excuse for higher prices by retailers.

Owing to freight transportation difficulties only one ferry per day is now operating between Cobourg and Charlotte.

Booth Company, Ottawa, are building a new brick stack 280 feet high and eleven feet inside diameter.

Grand Trunk shops in Montreal recently completed ten freight locomotives, and are proceeding with the construction of five passenger locomotives. In spite of these activities, the staff was recently reduced by 25 per cent.

Montreal.—On August 31st there had been shipped overseas from the port of Montreal 80,248,953 bushels of grain, which is a record. On Monday, August 28th, 1,569,393 bushels of grain had been loaded and dispatched overseas. This is believed to be a world's record for one day. Most of the grain being handled at present is from United States sources, but it is believed that Canadian grain in quantities will soon be coming through. New facilities have recently been installed which will permit of loading an additional 72,000 bushels of grain an hour. No cases of ocean tonnage demurrage have occurred this year. Only five lake vessels awaited unloading on August 29th.

A. H. Quigley, general manager of the Canadian plant of the Anaconda American Brass, Limited, who have taken over the plant and good will of Brown's Copper and Brass Rolling Mills, New Toronto, states that cutters and workers in brass and kindred industries may locate here as the result of the extension of the company's activities. While the future may develop a greater variety of products at the New Toronto plant, the output, at the present time going almost direct to manufacturers, consists of sheet brass in flats, strips and coils in various mixtures—high brass, low brass and bronze of 65 to 95 per cent. of copper—also copper in sheets, rolls and strips plain and tinned. The Anaconda American Brass, Limited, is the Canadian end of the American Brass Co., owned by the Anaconda Copper Mining Co. The Canadian company's officers are:—President, John A. Coe; vice-president, G. H. Allen, vice-president American Brass Co.; treasurer, C. F. Hollister, treasurer, American Brass Co.; secretary, M. S. Moss; general manager A. H. Quigley. Messrs. Moss and Quigley are the local directors on the board which in addition to the other officials named includes: John D. Ryan, chairman board of directors of Anaconda Copper Mining Co.; C. F. Kelly, president Anaconda Copper Mining Co.; B. B. Thayer, vice president of Anaconda Copper Mining Co.; and Charles F. Brooker, chairman board of directors American Brass Co.

ATKINS
METAL CUTTING SAWS

Solve your Metal Cutting problems, easily, quickly and economically, by adopting the products made by

ATKINS

We make Kwik-Kut Power Hack Saw Machines which use practically the full cutting edge of the Hack Saw Blade at each stroke; Metal Cutting Band Saw Machines for general shop work, cutting all classes of metal up to 12 x 14 inches.

Your requirements for Metal Cutting Circular Saws can be supplied promptly and we solicit a trial of our "AAA" Non-Breakable and Power Hack Saw Blades and Frames.

Canadian Representatives:
Chas. A. Strelinger Windsor, Ont.

Ottawa.—Government reports show a big advance in the production of steel for the month of July. The output in June was 32,805 tons and that for July 62,767, an increase of 91 per cent. The greatest increase was reported from the Algoma Steel Corporation mills at Sault Ste. Marie. They are working on a large rail order for the C. P. R. From the following average monthly production figures of pig iron, steel ingots, and castings in Canada for the years designated, it becomes apparent that while there has been improvement in each month so far this year, the industry has still some distance to go before getting up to the rate of production of pre-war years.

Average monthly production of pig iron, steel ingots, and castings in Canada, 1907 to 1916 in thousands of long tons follow:—

Year	—Monthly Average— Iron	Steel
1907	48	53
1908	47	44
1909	56	56
1910	60	61
1911	68	66
1912	75	71
1913	84	87
1914	58	62
1915	68	76
1916	87	106

Total production of pig, steel ingots and castings in Canada by months from 1920 to date, in the 1,000s of long tons, follow:

	1920		1921		1922	
	Iron	Steel	Iron	Steel	Iron	Steel
Jan.	73	92	41	40	32	33
Feb.	64	84	58	59	....	....
Mar.	69	97	60	53	34	42
Apr.	77	93	39	27	42	30
May	87	90	56	52	33	22
June	80	91	55	64	23	17

FIGHT AGAINST CORROSION

A leading British steel maker recently estimated that rust and other kinds of corrosion cost the world five hundred million pounds every year. This figure may be no more than a clever guess, but in any case the ravages of corrosion are so great that we are not surprised to learn that in Great Britain a proposal has arisen for the formation of an association of manufacturers of products which are non-corrodible and anti-corrosive. Support has been received from British firms making stainless steel, anti-corrosive paints, and various preservative compounds. The first step which this Association of Non-corrodible and Anti-corrosive Products will take is likely to be the organization of a public exhibition in London of non-corrodible and anti-corrosive products.

COMPACT PORTABLE PUMP

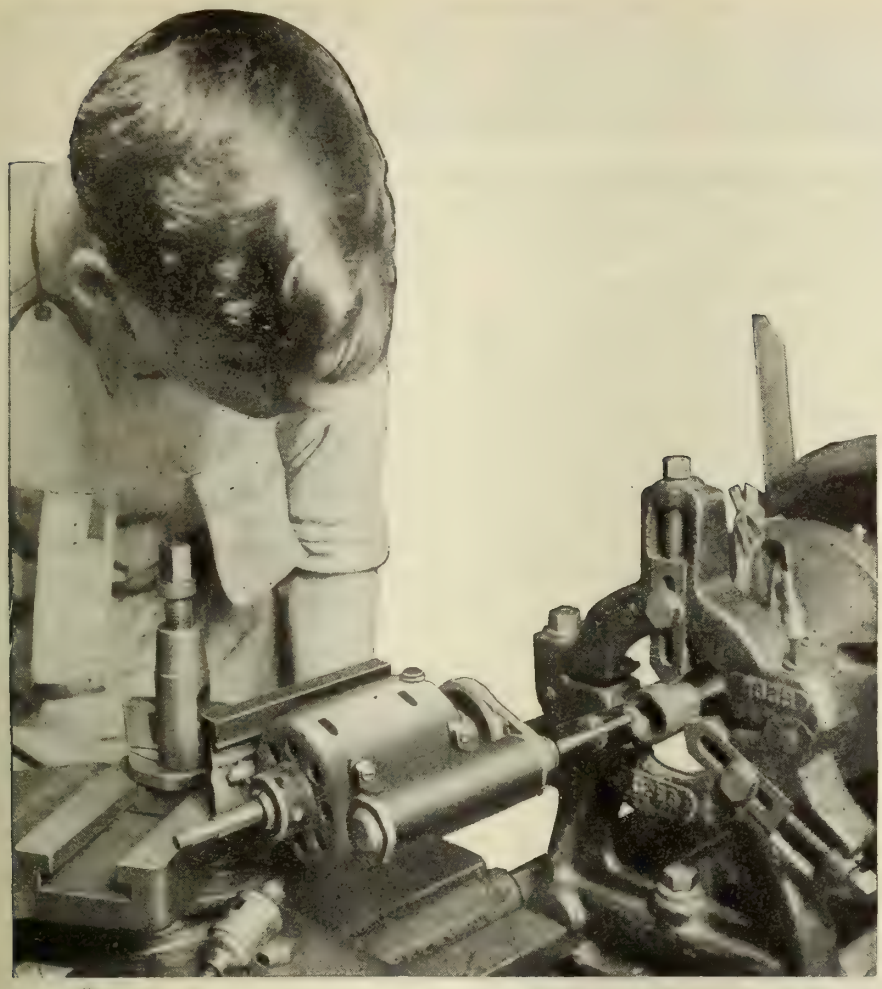
There was recently despatched to the Far East a portable pumping set specially designed to work in very constricted spaces. This pump carries a seven horse power paraffin engine; but it is so designed and mounted that it can be readily accommodated in a space 4 ft. 6 in. long and 5 ft. 6 in. high. The pump is capable of delivering 250 gallons per minute against a height of 30 ft. Water-cooling is provided, and in the event of the water available being dirty or otherwise unsuitable for cooling purposes, a radiator or fan can be brought into operation. With a view to easy transport the pump and engine are mounted on a frame with wheels, and the whole arrangement can be easily hoisted in a crane.

BURNING POWDERED COAL

Great interest has been taken during recent years in the use of coal in the form of powder. There is general agreement that such a fuel can be used to great advantage in many cases, but that the cost and other drawbacks of having to pulverise the coal may more than outweigh the benefits of using fuel in the powder form. The plant is expensive and the powdered coal cannot be stored without danger. These drawbacks are, however, avoided by the use of a new machine designed and manufactured by a British firm. This machine is self-contained and it dries and powders the coal and propels it direct into the furnace, so that there is no need to store the powdered coal or to instal plant to carry it from the grinder to the furnace. The machine works continuously and it dries and pulverises at the same time. All that an operator has to do is to feed it with coal. Tests of a most practical character have been carried out on this machine for a period of twelve months, and they showed that the cost of pulverisation was about 2s. 7d. per ton as against previous costs ranging from about 5/- to 10/- per ton. The tests also showed that a lower grade of coal can be successfully used with this pulveriser. The latest development in connection with the plant lies in the addition of a small amount of paraffin to the coal during pulverisation. Although the amount added is very small it has a remarkable effect when using coal of poor quality.

Giant Aero Engines.—The British Government have ordered six large aeroplane engines of 1,000 h. p. These engines develop their power at 1,800 r.p.m. They were designed and built by Messrs. Napier. There are 16 cylinders and they have been given bench tests of 30 hours with entirely satisfactory results. The weight is three pounds per horsepower.

Shortage of coal has caused a partial shut down to the rail mill of the Algoma Steel Corp. at Sault Ste. Marie, Ont. The period of shutdown is indefinite, as the possibilities of securing an adequate supply of coal is uncertain.



With a DUMORE High Speed GRINDER, jigs, dies, gages, bushings, etc., which have become warped during tempering, can be brought down to limits as close as .0001 in. This is but one of many ways in which DUMORE grinders serve thousands of mechanics daily.

Can 5,775 Be Wrong?

A SHORT time ago practically unknown—to-day, indispensable in the shops of 5,775 of the country's leading metal working industries! Such is the remarkable sales record of DUMORE High Speed GRINDERS.

What greater tribute to the efficiency of these grinders could possibly be given? Surely the judgment of over five thousand of America's foremost leaders of industry can be relied on!

You, too, can unhesitatingly choose a DUMORE as the *one* grinder for *all* your intricate grinding work. Their extensive use by many varied industries suggests their adaptability—their *continued* use in these various lines of work prove the efficient and satisfactory service they render.

DUMORE grinders are durably built in six useful styles and sizes. Combining perfect running balance with correct cutting speed, these compact, high-speed grinders work with a total lack of end play and absence of vibration Speed and accuracy are assured on the most delicate jobs—increased output and decreased production costs are a certainty with one or more of these DUMORE grinders in the tool room.

Their many advantages and conveniences —the economy afforded by their superior performance—result in re-orders from eminent industrial experts everywhere.

Let DUMORE grinders eliminate the need of costly tearing down of original "set ups" in your shop. Let us show you, as we have thousands of others, how a DUMORE can convert wasted moments into productive hours. Ask your dealer or write us direct for information that will aid you solve your grinding problems.

Modern Equipped Foundry for Rent

A WELL KNOWN manufacturing plant will rent their UP-TO-DATE foundry to responsible party. They will also take large proportion of foundry output.

The floor space in main foundry is approximately 140 feet by 60 feet, and building is well lighted and equipped with all modern facilities including 4-ton electric overhead crane, continuous elevated track, metal pouring crane, and compressed air lines at convenient points.

A 10-ton cupola in ideal central position is also installed, and in addition to the above features, there is an up-to-date mill room with large tumbling barrels, sand blasting machine, etc., also a first class core room with good sized ovens. A well equipped pattern shop is also included.

This foundry is located in an ideal manufacturing district in Toronto, and has a railway siding right to the door.

This is a chance of a lifetime and none but responsible parties need apply. Prospective customers will gladly be shown over this foundry as it can stand fullest investigation. For further particulars write Box No. 813, Canadian Machinery.

His Safeguard— a PHOTOSTAT Print

Even your most conscientious machinist doesn't have to "make sure" about any figures or lines on a PHOTOSTAT print. He knows that the print was made directly from the original drawing, not from a tracing, and

The PHOTOSTAT makes no mistake. It makes photographic facsimiles.

There is always the possibility of errors in blue prints made from tracings. PHOTOSTAT prints are absolutely accurate.

It takes hours and in some cases even days to make tracings and blue prints. PHOTOSTAT prints are produced in a few minutes.

Tracing takes a skilled draftsman. The operation of a PHOTOSTAT requires only a boy or girl.

Tracings and blue prints cost dollars. PHOTOSTAT prints cost cents.

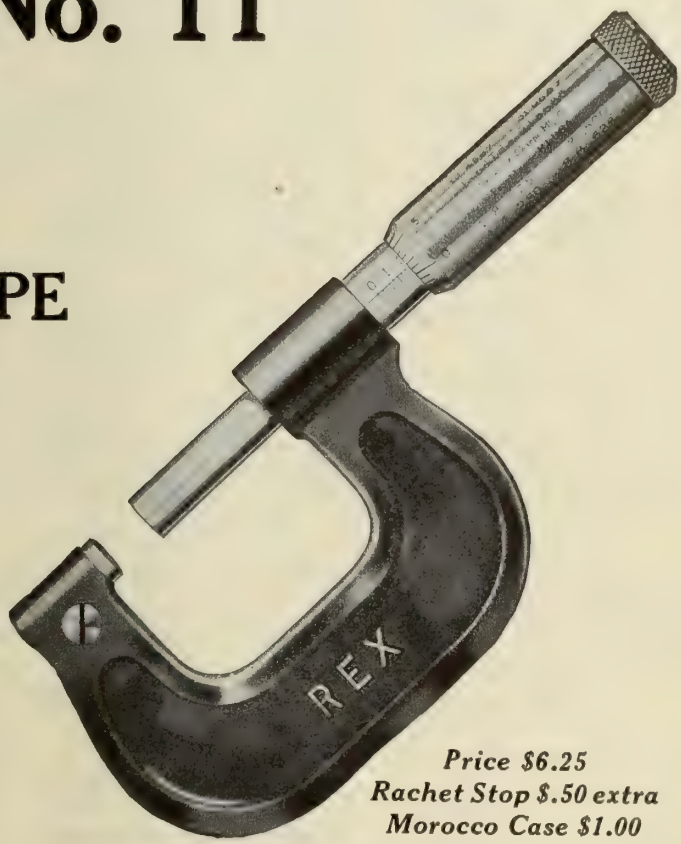
BROWN & SHARPE MACHINISTS' TOOLS

REX —No. 11

A ONE INCH BROWN & SHARPE MICROMETER



Price $6.25
Rachet Stop $.50 extra
Morocco Case $1.00

At a low price

This accurate, inexpensive measuring tool is admirably suited to the needs of machine operators. Its frame of I-section, combining strength with lightness, has a rectangular shape which gives larger measuring capacity than a frame of circular shape.

Machine operators will find constant use for this tool both in setting up work and in testing for accuracy during production. In the tool crib this micrometer will settle arguments about the size of bits, reamers, counterbores, etc. Encourage your men to use Rex Micrometers. More uniform accuracy of production will be the result.

There is a complete Rex line of micrometers in 24 sizes, covering a range from 0 to 24 in. These high grade measuring tools make available at a low price the Brown & Sharpe accuracy you have always known. Rex Micrometers will meet every measuring requirement of the busy shop. Write for our circular describing the complete Rex line.

Rex Micrometers are Brown & Sharpe Tools

For list of Dealers see the last page of This Buyers Directory

BUCKET CARRIERS, Pivoted
Can. Link-Belt Co., Toronto, Ont.

BUFFERS
Pryibil Machine Co., New York, N.Y.

BUFFING OR POLISHING MACHINES (See Polishing and Buffing Machines)
Blount Co., J. G., Everett, Mass.
Herbert, Limited, Alfred, Toronto, Ont
Petrie, Ltd., H. W., Toronto, Ont.
Pryibil Machine Co., New York, N.Y.
U. S. Electrical Tool Co., Cincinnati, O.

BUILDING MATERIALS
Bertram & Son Co., Ltd., The John Dundas, Ont.

BURNERS, OIL AND GAS
Rockwell Co., W.S., New York City.

BURRS
Steel Co. of Can. Ltd., Hamilton, Ont.

CABINETS, OIL
S. F. Bowser & Co., Ltd., Toronto, Ont

CALIPERS
Brown & Sharpe Mfg. Co., Providence, R. I.
Starrett Co., L. S., Athol, Mass.

CAMS
Canada Foundries & Forgings Co., Welland, Ont.

CAN-MAKING MACHINERY (See Sheet Metal Working Machinery)
Brown, Boggs & Co., Ltd., Hamilton, Ont.
Bliss Co., E. W., Brooklyn, N. Y.
Smooth Mfg. Co., Jersey City, N. J.

CARBONIZING
Chapman Double Ball Bearing Co., Toronto.

CEMENTS, IRON
CENTERING MACHINES
Bertram & Son Co., Ltd., The John, Dundas, Ont.
Garlock Machinery, Ltd., Toronto, Ont.

CHAINS (See Sprockets and Chains)
Reynold (Hans) of Canada, Ltd., Montreal, Que.
Wright Mfg. Co., Lisbon, Ohio.

CHUCKS, DRILL
Herbert, Limited, Alfred, Toronto, Ont
Jacobs Mfg. Co., Hartford, Conn.

CARD CLOTHING
D. K. McLaren, Limited, Montreal.

CASTINGS, ALUMINUM, BRASS, BRONZE, COPPER, DIE-MOLDED, FERRO-ALLOY, IRON, SEMI-STEEL, STEEL.
See "Where to buy your castings" Section. Page number may be found by turning to Advertisers' Index.

CHAINS, DRIVING
Can. Link-Belt Co., Toronto, Ont.
Greenfield Tap & Die Corp., Galt, Ont
Jones & Glassco, Montreal, Que.
Renold (Hans) of Canada, Ltd., Montreal, Que.
Wright Mfg. Co., Lisbon, Ohio.

CHASERS
Bertram & Son Co., Ltd., The John, Dundas, Ont.
Landis Machine Co., Inc., Waynesboro, a.
Pratt & Whitney Co., of Canada, Ltd., Dundas, Ont.

CHUCKING MACHINES
Acme Machine Tool Co., Cincinnati, O
Brown & Sharpe Mfg. Co., Providence, R. I.
Gisholt Machine Co., Madison, Wis.
Pratt & Whitney Co., of Canada, Ltd., Dundas, Ont.
Steinle Turret Machine Co., Madison, Wisconsin.

CHUCKS, DRILL AND TAP
Can. Fairbanks-Morse Co., Ltd., Montreal.
Canadian SKF Co., Toronto, Ont.
Cushman Chuck Co., Hartford, Conn
Geometric Tool Co., New Haven, Conn.
Pratt & Whitney Co., of Canada, Ltd., Dundas, Ont.
Skinner Chuck Co., New Britain, Conn.

CHUCKS, LATHE
Bertram & Son Co., Ltd., The John, Dundas, Ont.
Can. Fairbanks-Morse Co., Ltd., Montreal, Que.
Cushman Chuck Co., Hartford, Conn.
Herbert, Limited, Alfred, Toronto, Ont.
Geometric Tool Co., New Haven, Conn.
Gisholt Machine Co., Madison, Wis.
Ker & Goodwin Machine Co., Brantford, Ont.
Petrie, Ltd., H. W., Toronto, Ont.
Pryibil Machine Co., New York, N.Y.
Skinner Chuck Co., New Britain, Conn
Union Mfg. Co., New Britain, Conn.

CHUCKS, MAGNETIC
Pratt & Whitney Co., of Canada, Ltd., Dundas, Ont.

CHUCKS, PLANER
Bertram & Son Co., Ltd., The John, Dundas, Ont.
Cushman Chuck Co., Hartford, Conn.
Skinner Chuck Co., New Britain, Conn
Union Mfg. Co., New Britain, Conn.

CHUCKS, TAPPING
William L. Procunier, Chicago, Ill.

CHUCKS, VERTICAL BORING MILL
Bertram & Son Co., Ltd., The John, Dundas, Ont.
Gisholt Machine Co., Madison, Wis.
Skinner Chuck Co., New Britain, Conn
Union Mfg. Co., New Britain, Conn.

CLAMPS, MACHINISTS'
Brown & Sharpe Mfg. Co., Providence.
Starrett Co., L. S., Athol, Mass.

CLEANERS, METAL, WASTE, GENERAL
Oakley Chemical Co., New York, N. Y.

CLOCKS
Chicago Watchman's Clock Co., Chicago.
Hardinge Bros., Limited, Toronto, Ont.

CLOCKS, TIME
Gisholt Machine Co., Madison, Wis.

CLOCKS, WATCHMEN'S
Chicago Watchman's Clock Co., Chicago, Ill.
Hardinge Bros., Limited, Toronto, Ont.

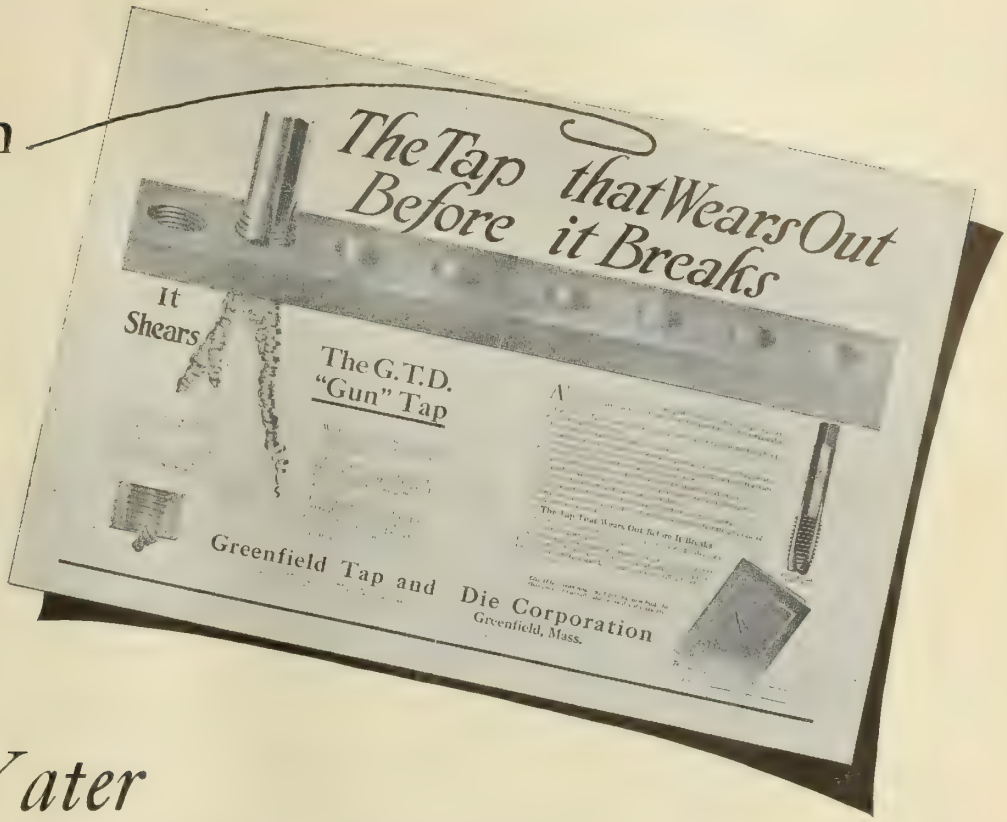
Since this Introduction Sept. 7, 1916



a Lot of Water Has Passed Over the Dam!

In fact, in the six years since G.T.D. brought out the epoch-making SPIRAL POINTED Tap, production tapping practice has undergone great changes. Millions of threads have been tapped at a saving, in every metal from lead to chrome nickel and monel and in these years the originators of the "GUN" Tap have accumulated a vast reservoir of engineering experience to aid their customers in meeting every conceivable tapping problem.

Many other makes of taps have been "improved" to follow up as far as possible the advance made by "GUN" patented features. The "spiral-pointed" tap is found in 1922 under many names—but there is still only one "GUN" TAP—the *original* spiral-pointed tap—brought out in 1916!

There can be no substitute for the six years of constant effort to improve the "GUN" Tap, that it might be not only "better" but absolutely the "best."—Nor for the results of hundreds of tests in different materials, which are on file for the benefit of "GUN" Tap users, tests which will help you in your own work—hence G.T.D. *continues* to be the world-headquarters for economy tapping.

REG U S PAT OFF
GTD

May we tell you what the ORIGINAL Spiral-pointed tap has accomplished on work like yours? No guesswork! Write to-day.

Tools That Cut Fast and Cut True

Butterfield Tools are the product of a great combination—specially trained men and the finest of special machinery. A close system of inspecting and testing ensures a high quality that is dependably uniform.

It is the "Butterfield Quality" that reduces breakages and eliminates a lot of grinding; that permits a finished, clean-cut appearance to the job; that is behind the reputation of Butterfield Products of being tools that cut fast and true.

TRADE P.M.S MARK
TORONTO, CANADA

To Select Good Belts

Look For This Trade Mark

It is our guarantee and assurance to you that the belting bearing it is the most desirable of its kind.

It is something more than a mark bearing our name and address. It means a lot of things. It says to you, in effect: Here is belting made of selected materials, by skilled workmen, under expert supervision. This belting gives superior adhesion to pulleys, even pliability, great strength, and remarkable resistance to the action of heat, cold or moisture.

ORATION
2nd St
EAN
March 29th, 1922
Oakley Chemical Company
26 Thames Street
New York City
Subject: Explanation of How We Saved $2700 a Year with Oakite
Gentlemen:
I now have before me figures showing how much it costs to clean our unit drive motors with Oakite during overhaul
We used to clean the motor parts by hand-scrubbing them with gasoline. The cost of labor and gas averaged $300 a month, and our machinists were never able to turn out a really good overhaul job. That is, their work was hampered by dirty parts, even after the most laborious hand-scrubbing, and the motors could not be put into absolutely first class operating condition
Since using Oakite, the cost of materials and labor dropped to $75 a month, and this means a saving of $2700 a year on this one item of cleaning. In addition, there is no fire risk attached to Oakite. The men like your materials better, and our motor overhaul work shows a big improvement over the past.
At the time I asked you to send one of your Service Men to check up on our cleaning work, I certainly had no idea Oakite would do so much for us. I thought we had our cleaning costs down to bed rock. Your representative asked for the exact figures as soon as I knew what they were. Hence this letter.
Very truly yours,
W. T. Johnson
Superintendent
WTJ/RFW
Perhaps you too could save money by doing this

DO YOU Manufacture Industrial Equipment?

Are you a manufacturer of twist drills, hack saws, mechanics' tools, wire guards, bolts, rivets, paints—do you manufacture lines of any description that can be used in machine shops, metal-working plants, power plants or foundries? If you do the publications you see illustrated here (Canadian Machinery, Canadian Foundryman, and Power House) can build a bigger demand for your products.

This group of technical newspapers is read by the men who are prospective buyers of your lines. You can bring to the attention of these men the reason why they should demand your goods when purchasing from their dealers. You can effectively do this by placing a message in the paper which serves the field in which your products are sold.

CANADIAN MACHINERY AND MANUFACTURING NEWS is published weekly and covers the machinery, iron and steel and general metal-working industries of Canada.

POWER HOUSE is published semi-monthly; it serves steam, electrical, water and gas power plants, and the power houses of all general manufacturing plants.

CANADIAN FOUNDRYMAN AND METAL INDUSTRY NEWS is published monthly; it serves the grey iron, steel and non-ferrous foundries.

Each one of these publications reach proprietors, managers, purchasing agents, foremen—the men who direct the purchasing of goods. A message to these men in any of the MacLean Technical Newspapers is certain to have a strong influence.

Write for complete Data.

Where Simplicity Means Accuracy

Just as a straight line is the shortest distance between two points, so a Bristol Recording Thermometer is the shortest route from temperature to record.

Simplicity, it happens, is the keynote of the accuracy in Bristol thermometers. The two are complementary and Bristol users appreciate one as much as the other.

It is this simplicity that makes Bristol equipment so popular with firms that buy for service. You will appreciate it, whatever your thermometer applications may be.

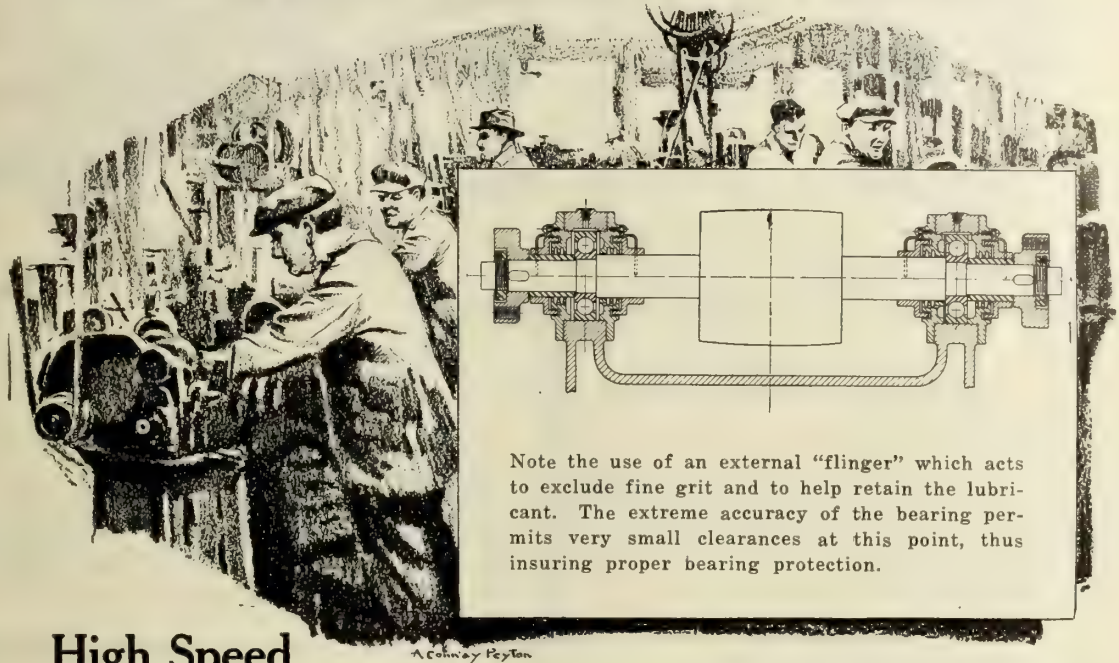
SKF

Modern Machine Tools



Note the use of an external "flinger" which acts to exclude fine grit and to help retain the lubricant. The extreme accuracy of the bearing permits very small clearances at this point, thus insuring proper bearing protection.

High Speed For Months with Practically No Attention

Double end disc grinders must be accurately mounted, well balanced and practically vibrationless to be successful. This means that the bearings must be almost frictionless and that wear must be kept at a minimum so that the original accuracy of both the bearings and the spindle may be maintained.

Manufacturers of double end disc grinders are finding that SKF marked ball bearings enable these machines to run continuously and without attention for long periods of time. The bearings support both the thrust and radial load as transmitted from the belts and grinding wheels and maintain high speed safely without danger of heating, binding or chatter. Even under the severest duty they are practically wearproof.

SKF marked ball bearings need no "take up" or adjustment and so little lubricant that replenishment once in several months is sufficient. In every way they make a trouble-proof part which increases the reliability and life of the machine.

What Bill says to Jim Doesn't Pay Dividends

When Bill meets Jim at the oil barrel, they are sure to gossip—for Bill has to wait while Jim fills his oil can. That's six minutes of your time wasted—three by Bill and three by Jim.

And oil is wasted, too—for oil overflows with the conversation.

Stop these wastes. Install the complete Bowser Oil Storage equipment. It is so flexible that it meets any need. All receipts and disbursements of oil are registered. Every drop of oil is clean—no grit can possibly get into the storage tank.

Write to-day for Booklet C-13 and let our engineers suggest the way you can save from 17% to 32% on present oil costs.

Bowser Equipment is MADE IN CANADA by

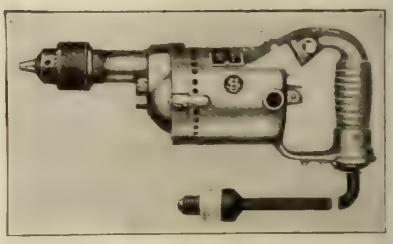
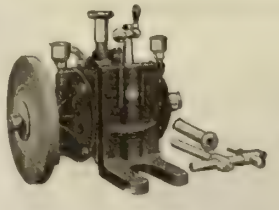
U. S. ELECTRIC
Drills and Grinders
Can be Attached to any Lamp Socket

For drilling in metal these drills are the superior of every other kind of portable drill. Their operating cost is only half that of air drills. And they can be attached to any lamp socket.





Made in several sizes from 3-16" to 1¼". Motors wound for alternating or direct current, or both, 110 or 220 volts.

A trial will prove that our drills and grinders will save you time, labor, and expense. Order a few today.

Specialists in Metal Working Machinery

Business is improving. Are you fully equipped to take care of your share of it? Worn out and old types of machines are only a handicap to showing profits. Look over your plant. See what machines you really need to increase your production and write us particulars. We will have a representative call upon you prepared to quote prices and give full information. We have a large modern plant located at 163 Dufferin Street, Toronto, for the re-building of used machinery and guarantee all our rebuilt machines to be in first class working order. At the present time have a large stock of rebuilt machines in stock, of all classes, ready for prompt shipment on which we can quote very interesting prices.

Let Us Quote on All Your Needs in New Machinery

To Holders of Five-Year $5\frac{1}{2}$ per cent. Canada's Victory Bonds

Issued in 1917 and Maturing 1st December, 1922

CONVERSION PROPOSALS

THE MINISTER OF FINANCE offers to holders of these bonds who desire to continue their investment in Dominion of Canada securities the privilege of exchanging the maturing bonds for new bonds bearing 5½ per cent. interest, payable half yearly, of either of the following classes:—

(a) Five year bonds, dated 1st November, 1922, to mature 1st November, 1927.

(b) Ten year bonds, dated 1st November, 1922, to mature 1st November, 1932.

While the maturing bonds will carry interest to 1st December, 1922, the new bonds will commence to earn interest from 1st November, 1922, GIVING A BONUS OF A FULL MONTH'S INTEREST TO THOSE AVAILING THEMSELVES OF THE CONVERSION PRIVILEGE.

This offer is made to holders of the maturing bonds and is not open to other investors. The bonds to be issued under this proposal will be substantially of the same character as those which are maturing, except that the exemption from taxation does not apply to the new issue.

Dated at Ottawa, 8th August, 1922.

Holders of the maturing bonds who wish to avail themselves of this conversion privilege should take their bonds AS EARLY AS POSSIBLE, BUT NOT LATER THAN SEPTEMBER 30th, to a Branch of any Chartered Bank in Canada and receive in exchange an official receipt for the bonds surrendered, containing an undertaking to deliver the corresponding bonds of the new issue.

Holders of maturing fully registered bonds, interest payable by cheque from Ottawa, will receive their December 1 interest cheque as usual. Holders of coupon bonds will detach and retain the last unmatured coupon before surrendering the bond itself for conversion purposes.

The surrendered bonds will be forwarded by banks to the Minister of Finance at Ottawa, where they will be exchanged for bonds of the new issue, in fully registered, or coupon registered or coupon bearer form carrying interest payable 1st May and 1st November of each year of the duration of the loan, the first interest payment accruing and payable 1st May, 1923. Bonds of the new issue will be sent to the banks for delivery immediately after the receipt of the surrendered bonds.

The bonds of the maturing issue which are not converted under this proposal will be paid off in cash on the 1st December, 1922.

W. S. FIELDING,
Minister of Finance.

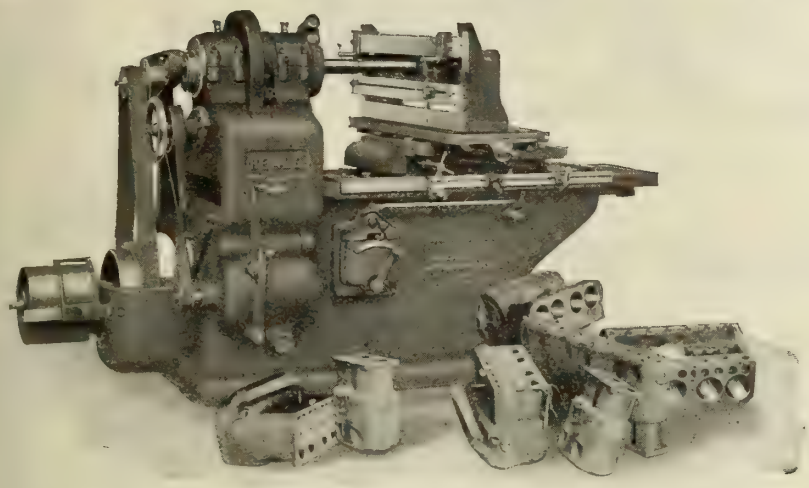
Cylinder Regrinding in Canada



A new Heald Style No. 50—solid base, extra wide, table mechanically driven, self contained, equipped with Heald universal jig,—it is an excellent machine for either manufacturing purposes or regrinding.

THE demand for reground cylinders by motor owners of the United States has resulted in the installation of over 1,500 Heald grinders in various parts of the country in the last two years. Small machine shops and individuals who have taken it up find it to be an unusually profitable business.

For the auto repair shops already established it not only is an excellent investment on the capital required but also the results are so satisfactory to the motor owners that they become definite customers and the shop's best booster.

While the same conditions hold true in Canada among those already established there are still several other localities which offer unusual opportunities to a good, energetic mechanic. Remember, however, that the heart of a regrinding shop is the machine itself and that without exception the successful ones in the States own Healds for they are designed and built especially for this work. Also, every motor manufacturer that grinds his cylinders uses Healds.

We would be glad to advise you candidly what the opportunities are in your locality if you will communicate with

VOL. XXVIII, No. 11 SEPTEMBER 14, 1922

Keeping the Industrial Plant Fit to Work In

Making Surroundings More Attractive to the Workmen—Northern Exposure Best for Lighting—Cleanliness Essential to Good Health—Working Conditions Affect Production—Welfare Work

A CENTURY ago all manufacturing of iron and steel products was done in comparatively small shops, and in consequence, many of the present day problems of sanitation and workman's welfare, that are present in the medium and large plants, were not encountered. Then too, many of the practices of to-day along such lines, were not known. One can imagine, however, that most establishments of those days were dingy, poorly lighted, and poorly ventilated. As the shops developed in size with the passing years, there was a correspondingly greater amount of attention paid to these problems. It was found by making shops more attractive, workmen were able to accomplish more work. Thus not only from a humanitarian standpoint, but also from a point of view of efficiency, it was found to be very profitable to study shop conditions with the idea of improving same.

Natural and Artificial Lighting

In a modern shop, after its location has been determined, one of the principal factors that are considered is one of lighting. The nature of the manufacturing operations, as well as special processes peculiar to the work being handled, are duly considered. All conditions being equal, when light enters through windows in the side walls, a northern exposure is considered best, in these countries so far north of the equator, because an eastern, southern, or western exposure always permits the direct rays of the sun to enter at some time during the working day, which is not considered a desirable condition, as in most seasons of the year these rays communicate excessive heat and tend toward poor distribution and diffusion of the light. In such instances it is invariably necessary to use some form of shade or awning to reduce the undesirable effects.

Outside Wall Construction

Some factory walls may be described as one steel frame to support the roof and carry one huge sash, about ninety per cent. of the area of the walls being glass. This is an extreme condition, but not infrequently seen. It is not the intention of the writer to condemn such construction, but it does appear that a product must, indeed, be delicately constructed, to require such a degree of light. Further it is sometimes suggested that the advantages do not offset the disadvantages, for machine shops. The large area of glass is exposing a very fragile surface to the risk of damage, from both external and internal sources. Then there is the probability of it not being weather proof, and even if it is initially so, it soon deteriorates, unless a great deal of attention is given to its maintenance. It presents a large area to be kept clean, and also allows, in our rigorous climate, a great deal of heat to radiate, in the severe winter weather. Structurally it is not the strongest construction. Its single advantage is the excellent lighting, if kept clean.

On the other hand one occasionally sees a shop where the windows are extremely small, representing but only a very small proportion of the area of the walls. One cannot lay down any hard and fast figures, but as a guide, if fifty per cent. of the wall area above a line four feet above the floor level were

Illustrations through courtesy of the Northern Electric Co., Montreal.

Individual light equipped with proper type of reflector.

Same machine with reflector removed showing bad distribution of light.

glazed, it would ordinarily appear that an area in excess of this, would give but little additional useful light. If the ceiling, or roof, were high, and manufacturing was conducted below a point say, six or eight feet above the floor, the figure just expressed would be excessive. The use of ribbed or frosted glass tends to better diffuse the light. The interior of all shops should be painted a dark color for a reasonable distance above the floor. Above that point a light color should be employed.

Skylight and Roof Design

Skylights, and windows in cupola or monitor roofs, are good methods of increasing the natural lighting. Some buildings are well lighted through the saw-tooth roof construction. In these roofs it is usually arranged to run the ridges east and west, have the southern slopes opaque, and the sash in the northern slope, which usually more closely approaches the vertical, and consequently is shorter in linear measurement. These last three methods are only applicable to one storey buildings, or to the top storey of buildings with several storeys.

Should it be impossible to obtain a northern exposure, there are many ways of overcoming the difficulties mentioned before, which only slightly reduce the efficiency of a window. Working under a skylight or window, with the rays of the sun beating directly down on one, is a very unpleasant task, except in the cold weather. Special shades and awnings do away with the difficulty.

Passing on to artificial lighting, one launches into a very large subject, which has occupied the attention of many organizations and many prominent men. The principle of indirect lighting has not been, to any great extent, applied to industrial buildings. The larger plants are commonly lighted by overhead electric fixtures, which are fitted with reflectors to throw the light downward. Incandescent electric lamps are usually used. These high power lamps are frequently nitrogen filled and are almost invariably found with tungsten filaments. The nitrogen filled lamps have their lower portions frosted, if the whole lamp is not frosted, in order to eliminate the intense brilliance, that is very trying to the eyes.

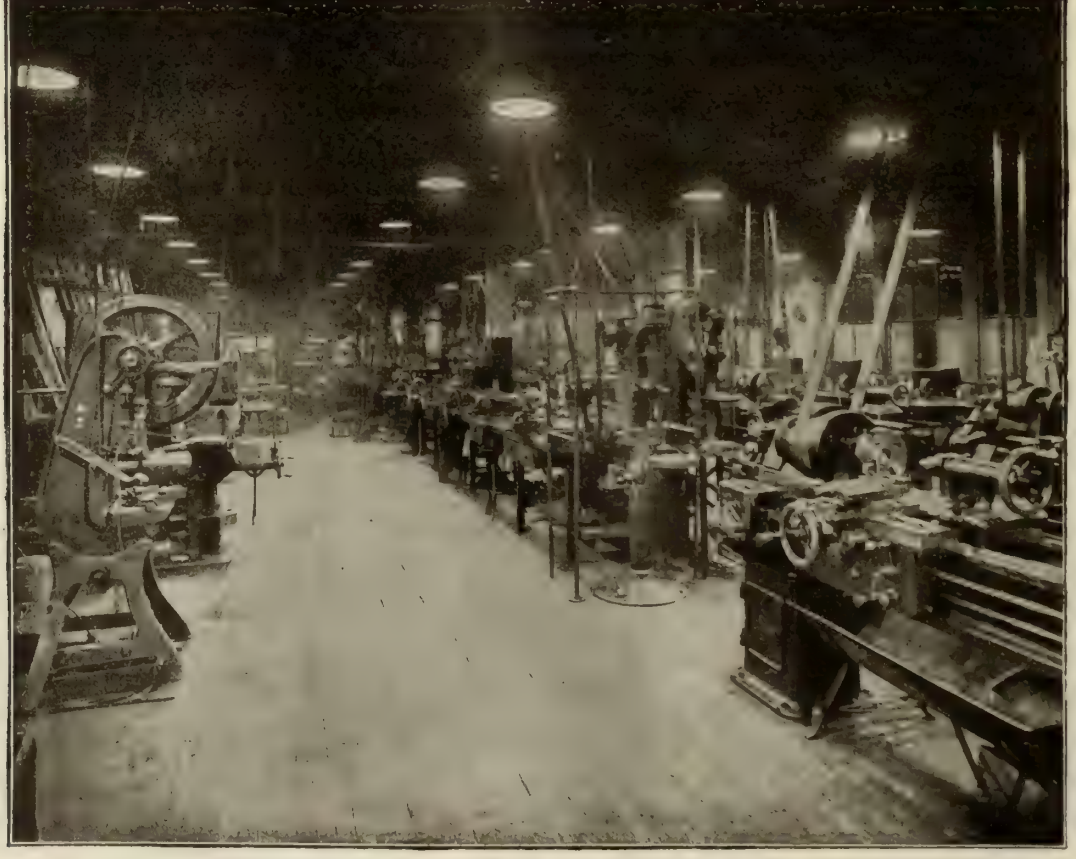
Mercury arcs are occasionally used to light factories, and several other applications have been more or less successfully tried out. The experience of the writer is that a 60-cycle alternating current is more restful to the eyes than the 25-cycle. This, however, is a point that presents a fruitful field for controversy.

Individual Lighting

To supplement the general overhead lighting it is almost a necessity to provide individual lights for each machine, and for each filer or bench hand. These individual lights are fitted with special holders or carriers, and long leads. It is always well to have wall plugs well distributed, enabling the leads to be plugged in at convenient points. In order that the provisions for lighting be most effective at all times, it is necessary to have machines and tools intelligently located, so that the best use can be made of both natural and artificial light. Actual records show that production has been increased from ten to twenty-five per cent. by the proper lighting of factories. The overhead expense of installing and maintaining good lighting facilities is small, when compared to the returns shown by the above figures of increased production.

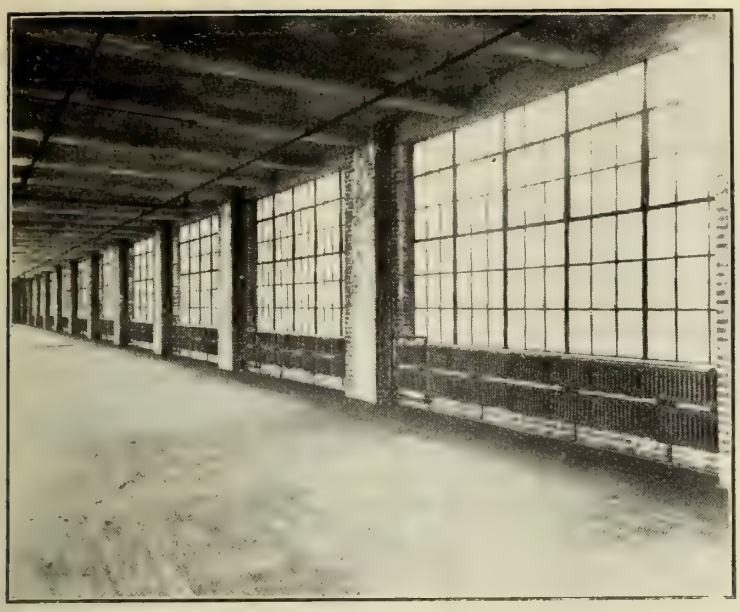
Ventilation

No man can do himself justice if he is allowed to work in a badly ventilated shop. Fumes from furnaces, or from the use of lard oil as a cutting compound on high speed machines, dust from snagging foundry castings, fumes from plating rooms, and dust from the wood working departments, should be expelled by exhaust fans from all shops. In the summer months the windows and doors provide for good ventilation. Windows in skylights or monitors provide an easy exit through which foul air is naturally expelled. In winter, when doors and windows are usually found closed, the ventilating problem presents more difficulties. There are many factories where there really is no attempt at installing a thorough ventilating apparatus. If hot air heating is the system employed, it is usual to have a fan pass clean air through steam heated coils and then pipe this warm air through the shop. This system provides for a good supply of fresh air at all times. If direct radiation is used to heat a building



Good example of properly lighted machine shop.

A well-lighted machine shop should have the illumination so distributed that the minimum amount of shadows will be cast around the machines. The arrangement of the overhead lights and reflectors should give the proper diffusion.



Manufacturing floor in Northern Electric plant at Montreal.

the only practical method is to install exhaust fans to remove the foul air.

The ability of workmen to apply themselves to better advantage in well ventilated shops is not questioned. It is, however, a rather difficult matter to express such convictions in actual figures. Some efficiency experts, have, nevertheless, done this, but to the average individual, the many varying factors employed to qualify the results, would cause the figures to convey but little concrete information.

Heating the Plant

There are many factories to-day that require steam in some of their manufacturing processes and are thus forced to maintain boilers. Other concerns use steam engines for prime movers. These firms usually install sufficient boiler capacity to also take care of their heating requirements. In this one instance, steam from the boiler, reduced to the desirable pressure, is passed into the heating coils, and in the other instance the exhaust steam from the engine is passed directly into the coils. Some firms have boilers which are used for no other purpose than for heating.

It is generally accepted to-day that steam is the best medium for heating large buildings. Two general methods of application are used, the first is by means of direct radiation from coils placed throughout the factory, and the second is to have the coils concentrated in a special chamber, and by means of a fan pass air through this chamber and on into conductor pipes, which deliver this warmed air to all parts of the factory. The first method is used where ceilings are low, and the latter method is used where ceilings and roofs are high. The temperature of a machine shop should be about 60 degrees F. if the mechanic is to work to best advantage. If a man is too warm he slows down, and if he is too cold he seeks warmer quarters at every opportunity. Thus maximum production is maintained when a constant temperature of approximately 60 degrees F. is provided.

Wash and Toilet Rooms

In connection with every wash room there should be a locker room where a workman can remove his street clothes, overcoat, and such other garments that he may wish to, before putting on his overalls. There should be sufficient wash room accommodation to permit all hands to wash up, in a reasonably short time, at noon and at the end of the day. The cost of white porcelain ware to-day is so reasonable, that this class of equipment is most usually provided. The ease with which this ware is cleaned is another good argument in favor of its use. The locker, wash, and toilet rooms should be put in charge of some particular individual, and he should be responsible for keeping them in order. A slightly higher temperature should be maintained in these rooms than in the shop. Warm water is a necessity. The workmen should have full use of these quarters, in as far as his requirements necessitate, but foremen should see that this privilege is not abused in any manner whatsoever.

Shop Cleanliness

In most shops good arrangements are provided for the removal of chips, cuttings and borings, from the machines. Unless this matter is taken care of regularly and systematically, a shop that might otherwise be in good order, appears slovenly. On those machines where cutting compounds are used it should be seen that all pans, piping, valves and connections are tight and are not leaking, as there are few more disagreeable messes than pools of lard oil or cutting compound on the floor of a shop. In addition to the unsightliness of it the machine operator often stands in it and gets his feet saturated.

Steel cuttings and turnings on the floor are not only hard on shoes but are very unpleasant underfoot. Oil slopped on machines, and carelessly spilled about, does not add to the attractiveness of a machine, and is a sure sign of carelessness. In fact an oil spattered machine is usually an indication of a careless and neglectful employee, and upon examining a spattered machine tool it is more often than not discovered that the machine has been given but indifferent attention.

Cement floors are very hard and tiring upon the feet of operators who are forced to remain standing throughout a shift. A small wooden platform placed on the floor will conserve their strength and enable them to attain greater production.

A miscellaneous accumulation of tools, jigs, straps, bolts, nuts, spoiled work, etc., etc., under and behind machines is an eye-sore to any self-respecting mechanic, and it is not reasonable to suppose that he can produce to advantage under such conditions of mental depression. Cupboards, racks, shelves, storerooms, and tool cribs should be supplied for all equipment, and it is the duty of foremen to see that all portable equipment is replaced each time a workman finishes the operation requiring its use.

There are many shops that provide all these receptacles for portable equipment, but at the same time have their machine tools badly arranged. In these shops the passageways are always cluttered up with work in progress. This condition of affairs is only one step removed from absolute untidiness, and is not conducive to workmen applying themselves to advantage. In every shop, one will always find workmen that eat their mid-day meal in the shop It is a good measure to provide for these men a small room, that they can use for this purpose. A table or two, and a few chairs, would answer the purpose.

Revenue Producing Factors

It has not been the purpose of this article to recommend any particular type of construction, method of lighting or heating, or of manufacturing. Rather it was decided that we treat upon the human side of these problems. Labor and capital have wandered far apart during the evolution of the big shops and interchangeable manufacturing. They have, to a certain extent, lost sight of each other's viewpoint, although they have many common interests. Everything has been figured out along mechanical lines, and the human side of the question has not been considered. It is the foregoing fact that has been capitalized by radical union leaders, and has resulted in the present misunderstanding between capital and labor. The average mechanic, if treated reasonably and made to feel that he has the confidence of his employer, can be depended upon to consider most things just as reasonably. If the shop conditions are such that he can do his work efficiently, surrounded by livable conditions, he is far more apt to pass over trivial difficulties, than he

(Continued on page 37)

Accurate Camshafts Produced by Grinding

Treatise on British Methods—Location of Master Cams—Dividing Head Forms Part of Attachment—Points to Consider in Obtaining Accurate Work—Provide Ample Support

By R. HARRISON

COMBUSTION engine manufacturers of to-day are generally familiar with the possibilities of precision grinding in connection with the production of their camshafts. The exceptional success, however, which has been realized with the attachments and methods set out below will doubtless appeal as a matter of considerable interest to both the production engineer and the man in the shop.

The grinding of cams, when made integral with the shaft, is accomplished by means of a self-contained attachment made in various lengths, arranged for mounting on the table of a plain or universal grinding machine. The attachment consists of an oscillating table carrying a driving head integral with it, the camshaft being mounted between centres, and supported by suitable steadies. The oscillating table is carried in trunnion bearings located on the table of the machine, and oscillates to and from the grinding wheel at each revolution of the work, the motion being positively controlled by a master cam.

Master cams may be of single, double, or triple form, but are always made from one piece of tool steel, the single cam being used where only one shape of cam is required, the double where inlet and exhaust cams are formed on one shaft, and the triple for camshafts on which the air-pump eccentric is additional to the inlet and exhaust cams. The master cams are generated, hardened, and ground to the correct shape, and with exact angular relationship between the inlet and exhaust, so that no variation can occur in use.

To take care of the varying number of engine cylinders, and their respective cams, a dividing plate forms part of the attachment. This plate is accurately divided corresponding to the number of cylinders used. The above combination of master cams with index plate covers any number of cams on the same shaft and reduces the operation of camshaft grinding to its simplest form.

The generating of master cams is an operation which cannot be efficiently carried out on the above attachments as it is impossible when working from a small model to reproduce with sufficient accuracy the necessary motion to generate the correct master. The grinding machine makers have special facilities and experience in the generating of master cams, and strongly recommend that users of attachments take advantage of same for the production of accurate master cams, all that is required being a correctly dimensioned drawing.

When ordering a new master cam it is essential that the makers be supplied with the following particulars together with any other data which in the user's opinion may affect the successful operation of the cam shaft which it is desired to produce.

Note.—The greatest care should be exercised in the preparation of the drawings to ensure that the shaft as designed will give the results required to conform to the predetermined fly wheel diagram.

It not infrequently happens that the makers are requested to provide master cams to conform to a fly wheel diagram which is not obtainable with the type of tappet mechanism provided, the most frequent sources of error in this connection being caused by a misconception on the part of the engine designer with regard to the points of tangency and contact on the cam motor. The error is shown magnified to an exaggerated degree in fig. 21 on the attached sheet of diagrams.

1. A complete working drawing of the cam shaft is required on which must be shown in addition to the usual complete dimensioning. (a) Direction of rotation when looking at driving end of shaft (b) Radial disposition of cams looking at shaft from the same position.

2. Type of tappet which it is intended to use in conjunction with the cam shaft. (a) Roller type (in which case diameter of roll must be given, (b) Mushroom type (in which case diameter of mushroom end and type of contact surface, whether concave or flat, must be given).

3. Disposition of tappet centre.

4. Clearance allowed in valve lifting mechanism (up to .010").

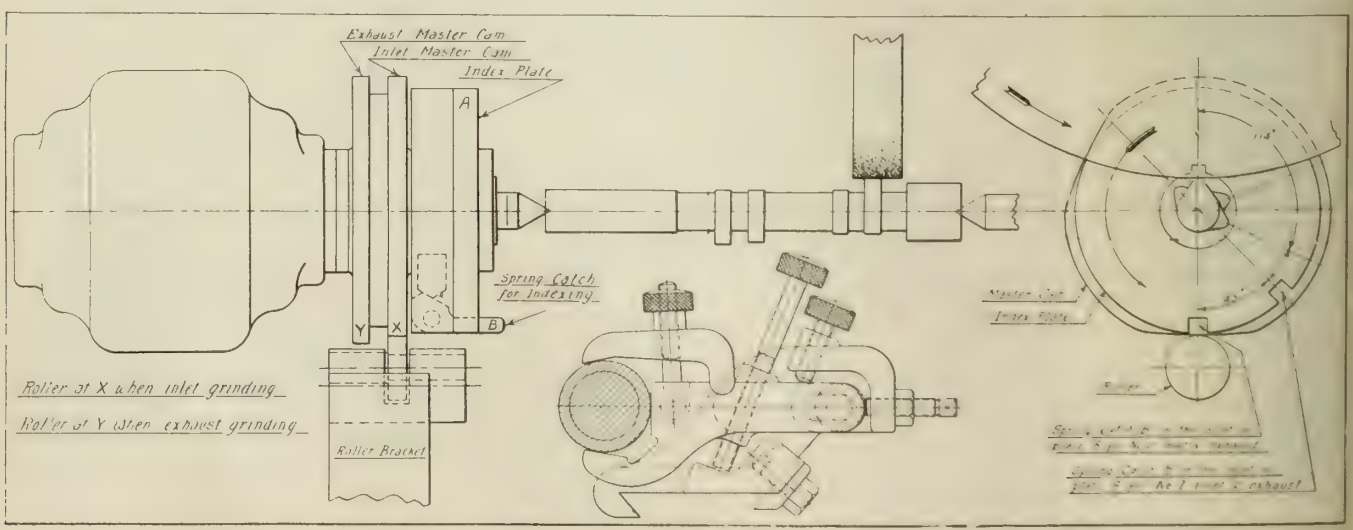
5. Diameter of roller on attachment

6. Diameter of grinding wheel on machine.

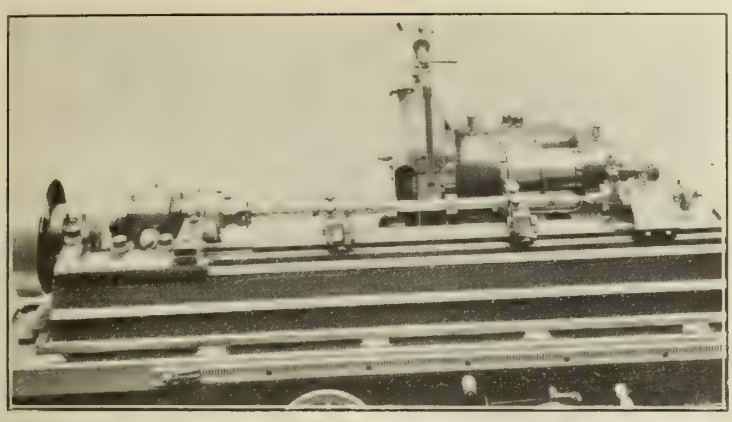
Items 5 and 6 not required when a new machine complete with attachment is being supplied.

Method of Operation

1. Centres.—The finished product can only be as accurate as the centres on which it is produced. It is therefore imperative that the centres in the attachment be ground to and maintained at the correct angle (usually 60°) and in addition be strictly concentric. The centre in the work should on the other hand be as large as possible consistent with the shafts being dealt with and should be made with a proper centre drill, this ensures adequate clearance to the point of the centre together with the correct



Plan view of the operating mechanism. Lower centre shows type of steady head used.



General view of the grinding machine.

angle. It should not be necessary to mention that both of the above be kept absolutely clean, but cases have been known where complaints re the production of inaccurate work has been directly traced to carelessness on the part the operator in not ensuring that the above simple precautions had been looked to.

2. Adjustment.—All working parts of the machine and attachment should be oiled at regular intervals and such adjustments made as are deemed necessary to ensure the correct functioning of the different movements. The master cam should be kept scrupulously clean on its working surfaces as should also the roller which makes contact with it. The two, however, should not be oiled on their contours when in use, as this oil tends to collect grit and dirt which make for the production of inaccurate work.

3. Steady rests.—There are always provided with a cam grinding attachment sufficient steady rests to take care of the longest shaft which the attachment will accommodate. The fullest use of these steady rests should be made and it should be seen that they properly support the wheel against the thrust of the grinding wheel.

4. Cutting compound.—Full advantage should be taken of the maximum amount of cutting compound available. This will keep the temperature of the shaft down, prevent local heating and help to prevent distortion. The power behind the grinding wheel and the sturdiness of the camshaft grinding attachment make it possible to economically produce an accurate cam-shaft from the rough turning, thus cutting out the form milling operation which was previously necessary to reduce the cam to within grindable limits. This enables a considerable saving to be effected in the total machining time necessary to give us the finished camshaft.

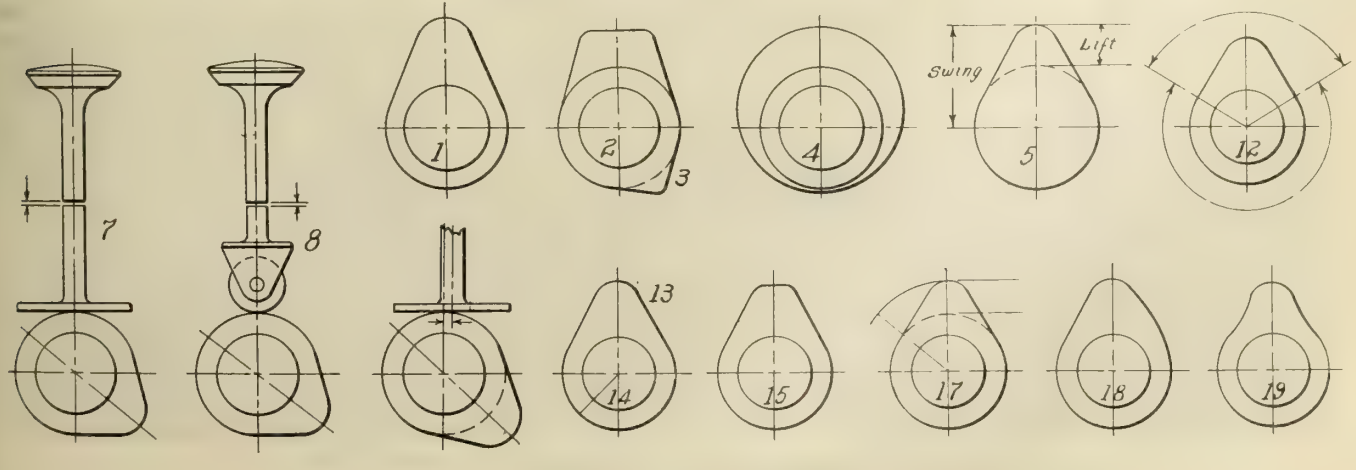
Roughing Out

Sequence of operations. No. 1. It is essential in all cases to first rough grind the cam shaft bearings and thus provide a true surface on which the work stays can operate. This operation is performed before the attachment is out on the machine. No. 2. Rough out inlet cams. No. 3. Rough out exhaust cams. No. 4. Rough out relief cam. No. 5. Rough out eccentric.

It is advisable in the interests of cheap production to put the work through in as large batches as possible, this saves time in changing wheels, etc. Using a moderately hard coarse wheel the average cam blank met with in present day motor car practice can be roughed down to within .015in. of finished size in three minutes. The actual allowance which it is advisable to leave on for the finishing operation depends of course on the steel from which the shaft is made. Where case-hardening heat treatment is adopted the allowance for final grinding should be kept uniform within the limits of a few thousandths of an inch throughout. Where the shaft is made from one of the alloy steels the texture of the steel being more or less uniform throughout, a greater tolerance as regards sizing in the roughing out operation may be allowed; .015in. to .020in. is the usual amount but no hard and fast rule can be laid down as each case must be judged on its merits if the most rapid production is to be obtained. The amount left for final grinding must, therefore, be varied up to or down as dictated by the experience gained with the particular design of shaft being produced.

The most rapid production of stock is effected by first roughing up the wheel surface by turning a thread across it with the diamond tool and then using the automatic wheel feed and a short fast table traverse under power, full advantage being taken of the automatic knock-off sizing device incorporated in the machine. Where the arrangement of the cams on the shaft is such that there is very little space between them the straight-in-feed method may be used with good results but in the interests of economical wheel wear it is advisable wherever possible to use the table traversing auto feed method. It is always advisable to commence grinding the cam blanks from the driving end of the attachment. This ensures that any possible interference in the angular relationship caused by torque will be kept uniform. It cannot be too strongly emphasized that the work must be very rigidly supported by the steadies provided for the purpose, and it is for this reason that the makers recommend that the journals be rough ground as a first operation. After rough grinding all over the shafts are heat treated and returned to the grinding machine for the final operation.

In cases where there are threaded portions on the cam-shaft some manufacturers who use the case-hardening method of heat treatment prefer to leave a surplus of metal on the portions which are to be threaded. This involves an intermediate lathe operation during the heat treatment as the shafts after carbonizing must be screwed before harden-



Various types of cams and tappets.

ing, the surplus of metal being first turned away and of course taking the carbonized skin with it.

Finish Grinding

This follows a sequence of operations similar to those employed in roughing and is briefly as follows:—1. Grind to within .005in. of finished size the two journals on which the work stays will operate, thus bringing them true with the new axis of the heat treated shaft (this operation is performed with the ordinary plain grinding equipment of the machine and does not entail the use of the cam grinding attachment). 2.—Mount the shaft in the cam grinding attachment and finish grind all the inlet cams with the master inlet cam making contact with the roller. 3.—Transfer the master cam roller to the exhaust master cam and finish grind all the exhaust cams. 4.—The same for relief cam. 5.—The same for air, oil or water pump eccentric. 6.—Remove cam grinding attachment from the machine and finish grind all journal wheel seats, etc.

Synopsis of Terms

Inlet Cam.—1. The actual cam which opens the inlet valve on the engine.

Exhaust Cam.—2. The actual cam which opens the exhaust valve on the engine.

Half Compression Cam.—3. This is an auxiliary small lift cam, usually operating alongside the exhaust cam.

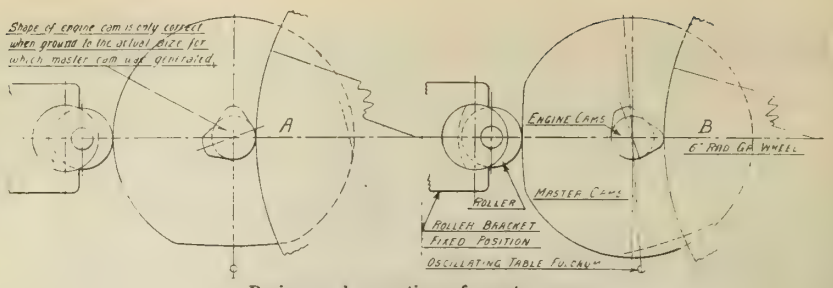
Eccentric.—4. This cam is sometimes fitted to the camshaft for operating either a water circulating pump or oil circulating pump.

Lift—5. Is the difference in height between the centre and circumference of the concentric portion and the centre and highest portion of the cam.

Tappet Rod.—6. This is that portion of the valve mechanism which transmits the motion of the cam to the valve stem. It is usually fitted with either a roller end or flat mushroom end.

Mushroom Type Tappet Rod.—7. This in shape resembles a mushroom and may be either curved or flat on the portion which comes in direct contact with the cam profile.

Roller Type Tappet Rod.—8. This is in shape a U-piece carrying at the bottom end a hardened steel roller which rolls along and transmits the motion from the engine camshaft.



Shape of engine cam is only correct when ground to the actual size for which master cam was generated
A
ENGINE CAMS
B
6" RAD GR WHEEL
ROLLER
MASTER CAMS
ROLLER BRACKET FIXED POSITION
OSCILLATING TABLE FULCRUM

Design and operation of master cam.

Clearance.—9. Is the idle distance travelled by the tappet rod before it makes contact with the valve stem (up to .010 inch).

Clearance Circle.—10. Is a circle so much larger in radius as the clearance indicated above i.e. the diameter of clearance circle equals diameter of concentric portion of cam, plus twice the clearance.

Fly Wheel diagram.—11. This is usually in the form of a circle on which are set out the various angles of opening and closing of the inlet and exhaust valves as controlled by the crankshaft.

Opening Angle.—12. This represents the number of degrees through which the cam travels from the time at which the valve it controls opens till it closes.

Toe or Peak of Cam.—13. This is the highest point from centre of cam.

Heel of Cam.—14. This is the concentric portion.

Toe or Peak Flat.—15. This is that portion which is sometimes arranged on inlet cams and often arranged on exhaust cams, which lies between the two radii enclosing the toe or peak.

Point of Tangency.—16. This is the point on the contour of the cam where the side of the cam becomes tangent to the concentric portion.

Contour.—17. This is the outline which indicates the shape of the cam.

Straight Side Cam.—18. This is a cam on which the sides are flat and can be represented by a straight line tangential to the concentric portion and radius of the peak.

Curved Side Cam.—19. This is a cam on which the sides between the two points indicated above are either curved outwardly or inwardly, when they are curved inwardly they are known as re-entrant curves. (The radius of these latter curves is limited by the radius of the grinding wheel employed).

Opening or Closing Points.—20. These are the points where, when all the clearances in the valve lifting mechanism have been taken up the valve starts to rise. It will be obvious that the point of contact and the point of tangency are never located in the same place when clearance is allowed.

Cam Grinding Attachment

Integral Cams.—22. This is the method usually adopted in present day automobile practice, where the camshafts are produced from forgings.

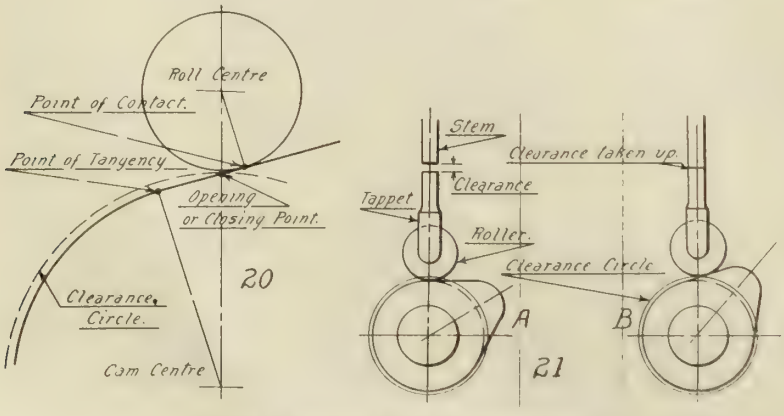
Individual Cams.—23. This type of cam is somewhat restricted to the larger sizes and is used mostly in heavy gas and Diesel engine design.

Model Cams.—24. These are exact duplicates of the theoretically correct shape cams used on the engine camshaft. The models are made exactly four times larger than the actual cams and are produced to very fine limits of inaccuracy. It therefore follows that when their shape is reproduced by the cam grinding attachment, any error in the model cam is reduced in the proportion of four to one.

Master Cams—25. These are the negative cams usually made two or three from high grade heat treated steel and represent in the negative form four times enlarged the contour of the engine cam. The master cams are made in the correct angular relationship with each other and being en bloc are therefore permanent. It is, however, possible to make slight alterations to them providing the cam which it is desired to produce does not differ to any great extent to that for which the master cam was originally ground.

Master Cam Roller.—26. This is a small diameter roller used on the cam grinding attachment to slide in contact with the various contours of the master cams and thereby transmit an oscillating motion to the swinging table of the attachment. This roller is hardened and ground to the same diameter as the small grinding wheel which is used in generating the master or negative cams.

Dividing Plate.—27. This is an accurately finished plate notched in the correct angular relation to which the finished camshaft contours must conform to meet the requirements called for on the fly wheel diagram. By the use of this dividing plate it is therefore possible to produce a six, eight or twelve cylinder engine camshaft from the one master cam.



Details in connection with cam construction.

Success in Combating Accidents at Algoma Plant

Special Educational Features of Great Assistance—Getting the Co-operation of the Employees—Big Reduction in Time Lost Through Injuries—Accident Investigation and Home Visiting

CARELESSNESS is accountable for a very large percentage of the accidents that occur in industrial plants. This has been proven time and time again. The human factor is the one element that prevents the attainment of complete success in the absolute elimination of hazard from life in its many and varied phases. Numerous attempts have been made and will continue to be made by those interested in the safety movement to adpot means for minimizing accidents to factory workers, and in a great majority of cases the results have been very encouraging, but just when we feel that a certain difficulty has been surmounted an injury is reported that sends our castle of optimism tumbling to the ground. The cause of the accident when investigated is found to be, not the faulty construction of machine or equipment, but the momentary failure of that human factor which makes the solution of the safety problem almost impossible.

In order to obtain an equation where the uncertainty of the human factor will be less of an unknown quantity, and one that we can take into consideration for finding an answer to this momentous question, it is essential that the workmen themselves be educated to the imperative need of adequate protection and of their own responsibilities in any scheme of accident prevention that executives may promote.

Reducing Accident Hazard

In this connection it is interesting to note the progress that has been made in regard to the method adopted by the Algoma Steel Corporation for obtaining the co-operation of their workmen for reducing the hazard that is generally associated with the operation of steel mills and similar activities. Comparative records indicate that they have achieved remarkable results in reducing the number and the severity of injuries sustained. For eleven months ending November 30, 1920, the number of accidents in which time was lost reached 571, while for the corresponding period in 1921 similar accident records showed that only 174 employees were injured. This figures out at a 69 per cent reduction. Owing to the fact that the operating staff for the last period was only about two-thirds of that employed during 1920, the above figures may not seem conclusive, but when calculated on a basis of full time operations the rate figures are 1.64 per 100 in 1920 and .84 per 100 in 1921.

Severity of Injury

The severity of an accident is based on the time lost as a result of the injury. This is considered by experts as one of the most vital factors in all hazard statistics. It is in this class of accidents that Algoma claims to show the beneficial results of their safety policy. For the eleven months in 1920 the records indicate a total loss of 10,772 days as a direct consequence of accidents. For the corresponding period of last year the time was reduced to 2,985 days. This shows an approximate reduction of 72 per cent., a remarkable and creditable showing. The compensation figures for the respective periods were roughly $95,772 for 1920 and $32,089 for 1921, a decline of over 66 per cent.

Replacing Absent Workers

Other factors must be taken into consideration when men are absent from the plant on account of injury. Temporary replacement is necessary to carry on the regular work. Very often a new man must be employed so as to maintain the efficiency of the organization. If an experienced man can be secured the drop in production may be very trivial, but if the right man is not available the time required to teach the new hand the duties of his office may entail a loss in output far exceeding the wage he earns. It has been stated by Algoma officials that approximately $250 a week has been lost on different occasions due to disorganization of a certain group of men carrying on specific work. The capacity of the new man very often determines the speed of the others, as a gang of men may be likened to a chain, where the strength must be reckoned as that of the weakest link. Therefore, the saving effected by the reduction of accidents is much greater than that represented in the actual compensation cost and minor losses resulting therefrom. On the other hand the uninterrupted operations of a well-balanced gang, everyone of whom is thoroughly alive to the disastrous results of industrial accidents, will maintain production at such a rate as to make the saving almost inestimable.

Creating Spirit of Goodwill

Mass psychology is a study well worth while for the large manufacturer. The employer who is vitally interested in the welfare of his workmen, and takes the trouble to show it, will create a spirit of goodwill and co-operation among the men which will react to the benefit of all concerned. They look upon him in a more friendly manner, realizing and recognizing that his efforts in their behalf are not solely with a view of acquiring increased wealth. The mind is undoubtedly the controlling force of all bodily action, so that a contented mind will influence the physical efforts of the body under its control.

Specific Case

In this connection it might be well to emphasize the importance of mutual understanding when some phase of safety work is contemplated. Too fre-

General view of the blast furnaces at plant of Algoma Steel Corporation.

quently we see guards and other protective appliances placed on machinery and dangerous places without consulting the wishes or desires of the parties for whom the protection is installed. The writer has in mind the installation of a special guard on a sheet metal punch press. Several accidents had happened on this particular press and it was decided to place a guard on the machine. When the device was ready to instal the man was given another temporary job until the guard was fitted in place.

In this particular shop a lot of the press work was done on the piece work basis, so when the operator was brought back to run the machine he did not take kindly to the protecting guard owing to the fact that it seemingly hindered production. The mind of the man had his body under submission. He seemed determined that the guard would hold up production to a prohibitive extent and for a time he had the foreman of the same opinion, with the result that the guard was seldom or ever used during a period of non-accident. However, a minor injury to the workman on one of the other presses again brought the subject of protection to the fore. This time the foreman had a talk with several of the press hands regarding the advisability of using protective guards.

Considering Suggestions

To try and offset the arguments of the men the foreman asked if any of them had any suggestions for press protection. One of the operators came forward and stated that he thought a slight alteration in the design of guard would secure better results. Believing he saw where he could get co-operation the foreman had the suggested modifications made to the original guard and when again fitted to the press, the success of the device was immediately evident, as the operator demonstrated that the efficiency of the apparatus was more a matter of human adaptability than mechanical defect. The mere fact that he had been consulted and his suggestion taken into consideration was sufficient to gain the goodwill and open mind of the worker, and in a short time the rate of production not only attained the old figure but in some instances surpassed it, as in time the operator gained confidence in the protective qualities of the guard and came through with increased production.

Safety Work Publicity

At the Algoma plant the essence of success appears to be in the publicity that is given to the general safety movement in and around the plant. This publicity is carried on in every conceivable way. By publishing in the local papers, decreases in number of accidents or no accident reports in specific mills, with, if possible, the name of superintendent or foreman. By keeping safety first in the public eye and by issuing periodical statements of the work being done. The house organ of the Algoma Corp., is probably the most effective unit in the whole scheme of the safety educational movement. This plant magazine equals anything of its kind in Canada, as the executives believe that what is worth doing is worth doing well. The engravings used are of the very best and the paper is of high-grade, coated surface. The publication is edited in such a manner as to create a permanent interest on the part of all employees, the friendly and good humored feeling being one of the most beneficial results obtained from the expense and effort of the monthly organ.

Instructing New Men

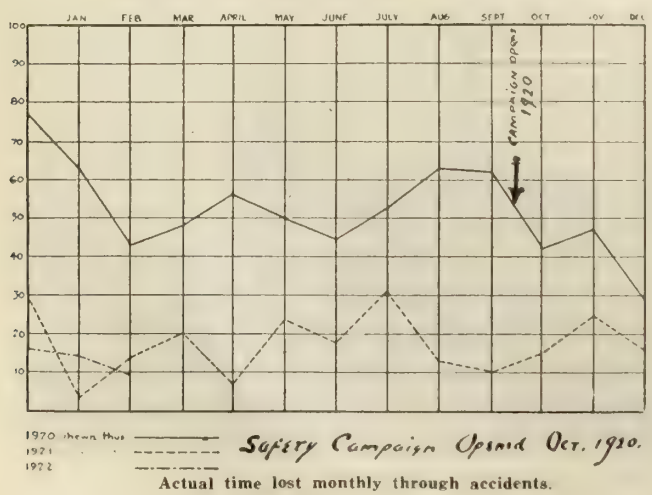
One of the principal features of the system and one that impresses the beginner with the thoroughness of the accident prevention move is the short course of safety instruction given to those starting into the service. A safety demonstration room, wherein all new men must pass at least half a day, getting instructions as to certain dangers in particular parts of the plant in which they will be called upon to work. The object of these instructions is to impress upon the workman the need for caution and to get him to realize that he is a unit in the scheme of better protection and that THERE IS DANGER in many sections of the plant provided he does not act cautiously and judiciously in the performance of his various duties.

The institution of an accident investigation system whereby every accident, no matter how slight the injury resulting therefrom, or even if no injury has resulted to an employee, has proved very effective in preventing subsequent mishaps from the same cause. The investigators are members of the safety department and it is their duty to make out a written report in every case—the essential facts covering who, what, how, when, where and why. In answering these questions the investigator is under instructions to interview all witnesses, getting each to recount what transpired at the time of the accident. If it is shown that carelessness has had a part in the accident the name of the responsible person is incorporated in the report. Several of these reports are made out and sent to the different departments interested for permanent record.

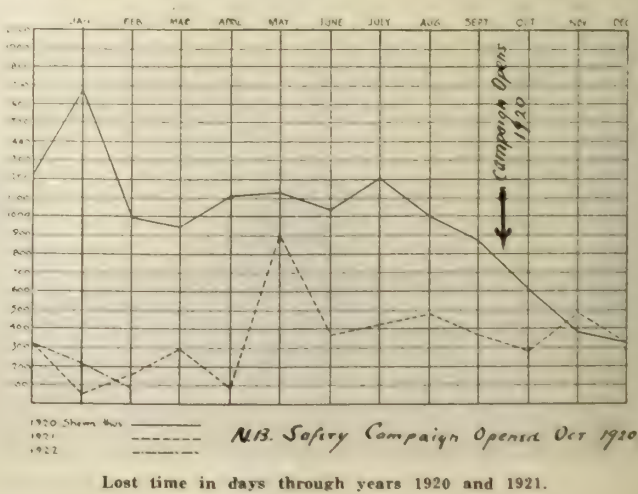
Immediately a man is injured he is given medical or surgical attention by the plant surgeons who are constantly on duty. It is the duty of these doctors to forward a report each day to the safety department, covering the details of their work for the previous day. To avoid any malingering of accident cases close tab is kept on every man injured and to the possible duration of off time, the number and time of periodical dressings, etc. The idea back of this was to eliminate a condition of affairs whereby men who had been injured, but who were able to return to work, were in the habit of staying away from the plant and drawing compensation at the expense of the company, though they had no right to such compensation.

Visiting the Home

In addition to the system as carried out at the plant the corporation has instituted a home-visiting plan whereby a member of the safety department visits the injured man in his own home and sizes the case up for himself. It has been found that many men who were able to return to work were putting it off in the hope that they would get a few days more with compensation. Every evidence points to the fact that the safety movement policy as adopted at the Algoma plant has been highly beneficial both from the standpoint of physical health and economy.



Actual time lost monthly through accidents.



Lost time in days through years 1920 and 1921.

Overcoming Some Faults in Babbitt Bearings

Proper Lubrication Very Necessary—Properties of Graphite—Causes That Produce Friction—Faulty Bearings Frequently Due to Carelessness—Keeping the Metal From Sticking to Mandrel

By W. S. STANDIFORD

AN IMPORTANT point in regard to lubrication is due to the weight of moving parts, these having a great influence in the proper lubricating of bearings, especially when the latter are made out of brass. It is well known among lubrication experts that the consistency of any grease or oil has to be suited to the weight and rapidity of motion of different machine parts; a lightly constructed machine such as a watch requiring a very thin oil to enable it to run properly. On the other hand, a thin oil proves to be decidedly unsatisfactory for heavy parts, as it is squeezed out by their weight before it can get in efficient work, thus allowing the bearing to heat up and "freeze" as it is technically termed, due to the heavy expansion of brass. Taken all in all, experience shows that babbitt-lined shells will give better results with the general run of lubricants on the market, as babbitt is, of itself, a more greasy-feeling metal than brass.

Safety Factor of Babbitt

It must not be construed from the above, that brass is unsuitable for making bearings; it being one of the best materials widely used and gives good results when rightly looked after. What the writer intends to convey is the fact that babbitt will withstand more abuse than brass before a bearing starts to cut from the stopping up of an oil-hole or carelessness upon the oiler's part; in forgetting to attend to bearings. There are some excellent oils on the market which contain graphite in suspension that give splendid service, conferring not only the lubricating properties of the oil to a bearing, but also the graphite. They are made in various degrees of viscosity. Greases are also combined with graphite; both oil and greases with the latter material added are well worth their money as a longer life is imparted to both brass and babbitt bearings.

Qualities of Graphite

To those who are not acquainted with the properties of graphite and the way that this substance prevents friction, a few pointers about its lubricating qualities will be of interest. Owing to its nature, graphite works on an entirely different principle from grease or oil and it is the best lubricant of all for heavy-moving or light parts. The theory and practice of all lubrication, regardless of the substance used for the purpose is, to keep two surfaces apart and prevent, as much as possible, their rubbing together as all metals are never smooth. Viewed under the most powerful microscope, the most highly polished pieces of any metal resemble a section of very coarse-grained sandpaper, there being many pin points sticking up, all pores in metal and also tool marks and other irregularities showing greatly enlarged, which taken altogether help to produce friction.

What Wear Means

When the oil on a bearing squeezes out, these irregularities and pin points interlock with the pin points getting broken off; this is termed wear. Tiny particles of the metal are then carried by the oil into the bearing parts and thus act as if an abrasive were added to the oil. The use of a grease or oil containing graphite entirely overcomes this state of affairs; the higher the percentage of graphite the substance contains, the better it acts. The graphite first fills up all pores and tool marks of the metal by being rubbed into them, after which a thin veneer of graphite is then placed over the entire wearing surfaces. When this veneer of graphite has been obtained, all friction will have been reduced to the lowest possible extent known to mechanical engineers. Another factor that helps to prevent undue wear on the bearings is, that the latter having become coated with graphite as is also the journal, the contact is now between graphite and graphite and not metal to metal.

To give an idea of the value of this material as a lubricant in reducing friction, the following test is instructive and interesting. Take two small pieces of uncalendered paper and lay one upon the other, then try to move the top one over the other by applying weight and force. It will be found to be difficult to move them as friction is holding both sections of paper together. Next take some flake graphite and rub some of it thoroughly into the pores on both sheets of paper; placing the two surfaces together and move them the same as was done before. You will now find that both pieces will move easily one upon the other, and also discover the fact that the more weight that you apply, or using other words, the more work that this graphite has to do, the easier both parts slide upon one another. Unlike oil, graphite cannot be squeezed out from between parts under any circumstances whatever. The above test illustrates one of nature's laws that, irrespective of weight, a graphite film cannot be squeezed out from between bearings, no matter how heavy pressure is applied to effect it, but remains at the point of contact; as a matter of fact the more weight that is applied, the firmer this material becomes embedded into all metal pores, the result being that all bearing surfaces are made extra smooth by its action.

An Ideal Mixture

As babbitt is by nature a more greasy substance when compared with brass, the use of a graphited grease or an oil containing it comes about to be as near an ideal mixture as can be expected, considering the rapid way all machines are worked so as to obtain increased output. In regard to the actual work of babbitting boxes, the machinist's or millwright's gang should take the greatest care so as to get best possible results, as any carelessness in handling it not only injures the babbitt's quality, but causes the poured bearings to wear out very rapidly and thus makes renewal necessary with its additional expense and loss of time that could be put to better advantage in doing other work by the maintenance forces of mills and factories, as it often occurs that these repair forces have two or more urgent jobs that need attention at the same time.

Where The Fault Lies

Another factor in babbitting work is due to the readiness in which the average run of workmen "lay the blame upon a metal's quality," it being said to "be inferior" when, as a matter of fact, the fault is entirely with the workers and their methods of handling. The finest quality of babbitt ever produced can be made to appear as if it were a cheaper grade and worthless. Mill foremen being as a general rule, very busy persons, have to depend to a large extent upon what their employees say about a babbitt's quality, they not knowing the conditions under which it was heated and poured, while others have a very hazy idea in regard to the fine qualities, or otherwise of this metal. For the information of this class of men as well as for their workmen who, in the vast majority of cases, are fair-minded and desire to do effective work and only put the blame upon a metal's quality because of sheer ignorance, this list of difficulties encountered and the proper remedies to overcome them are appended, which will, no doubt, also be of interest to all classes of factory men, as a better understanding of bearing materials will be of great advantage in regard to the long life of all bearings lined with babbitt and also to the keeping of machines in action so as to give the least amount of trouble.

(To be Continued)

Records Show Better Business in Machinery Hall

Interest in Wood-working Machinery and Good Sales Were Made —Prospects Encouraging—Sales Work Has Its Result After Year's Lapse—Complaint About Exorbitant Power Charges— New Engineering Building Badly Needed

ORDERS and enquiries received in Machinery Hall at Toronto Exhibition this year, show a marked improvement over last year's record, according to statements made by exhibitors. It would appear that many display their products, not because of any direct return, but because of the prospective customers which it develops. Others exhibit in anticipation of both sales and prospects and, as a rule, have demonstrations on hand and machines in operation. The variety of products represented this year was large and inclined to specialization. That is, there were no general displays of machinery or equipment. Every booth had an outstanding feature and it must be said that this added to t e general interest and helped promote actual business.

* * * *

Some exhibitors report sales from unexpected sources. Thus, when the representative of a firm making pneumatic tools went to considerable trouble last year to demonstrate a certain hammer to a prospect whom he had never seen before, he paid little heed to probable comeback. This year, the same man returned and declared that he had made up his mind to purchase such a hammer—which he did. Another firm reports a purchaser, last year, from Australia for a machine which he had demonstrated, and that a few years ago several sales were made to Australian buyers who had taken in the Fair. A manufacturer of transmission equipment states that a prospect with whom he discussed friction clutches last year dropped in this year and placed a rather respectable order.

* * * *

Considerable enthusiasm centered in the immediate prospect of a new Engineering building. Exhibitors are undoubtedly handicapped for space and demonstrating equipment. The task of placing and removing heavy machinery is a difficult and expensive one, and the inadequacies of display have further combined to discourage many large exhibitors who would otherwise be very much in evidence. Further, the cost of special electrical connection for motor-driven machinery strikes the exhibitor as a rather stiff item. Ten dollars per horse power for an exhibit where probably there would not be five-dollars-worth of juice used, is a big item, and one for which it is often hard to find an offset in the amount of business actually done. Line shafting does not always answer the purpose for such displays, and further, there is only a limited amount of this available in the old building. Each direct connection is a separate proposition and calls for an amount of expensive work by the electric companies. To make a block of power available for Machinery hall and to include individual costs in the booth rented, would appear to be advisable, but here again, the building hardly lends itself to complete electrification so as to suit the many changes in location and requirement. Some remedy may be worked out for 1923, but nothing short of a new building with all facilities for handling, shipping and demonstrating, will be completely satisfactory. The prospects looking to this most desirable objective in 1924 will undoubtedly meet with hearty support from manufacturers and engineering concerns.

* * * *

Woodworking machinery was a feature of the reported sales activity. It is evident that demand in this department has considerably more strength than in machine tools. The showing of the latter was by no means representative, and enquiries had particular reference to light equipment and accessories. In woodworking machinery, however, it was different. One exhibitor, three days before the close, had sold a variety saw, a band-saw and a 16 in. jointer, and had a number of sales in prospect before the close. Another manufacturer had disposed of a sander, a chisel mortiser and saw mortiser. A display of woodworking equipment adapted to the purposes of builders and contractors brought in several sales including planers, floor sanders, saw table and combination woodworkers. A dealer reported sales of two woodworkers, two adjustable saw tables, a small metal-working lathe, and other light equipment, besides many prospects that were very encouraging. There were a number of cylinder-grinding machines in demonstration and it is learned that in each case the demonstrator was sold. A light portable cylinder grinder was on display and satisfactory business was reported. Considerable interest centered in garage equipment. Included in a dealer's display was a universal tool, combining facilities for turning, boring, horizontal milling, vertical milling, drilling, tapping and reaming—a complete machine shop in itself, adapted for the small manufacturer, the garage, steamship or repair shop where space is at a premium.

Extensive displays of welding apparatus were featured and demonstrations were interesting. Quite a few sales were made not only of the larger, more expensive equipment, but more especially of the outfits designed to meet the more limited purpose or restricted requirements.

* * * *

Interviews with manufacturers of belting indicate this to be a department where, usually, sales run into very small items, where the large buyer does not put in an appearance because he feels that he will be well taken care of. Yet, some fairly good sales are recorded. There was a more representative display by belting firms this year. One large concern which had not found it possible to display during the past five years owing to shortage of stock, was on hand this year with some high-grade leather belting.

Transmission people state that, while Canadian belting has always represented high standards, some recognition is being accorded in this country to the new specifications for leather belting issued by the U. S. government. These represent concerted action by manufacturers and consumers of belting and have for their design a satisfactory and substantial quality on which competition could be fairly based. It is pointed out that a good many specifications in the past, created largely by the buyer without reference to the views of the maker, have been somewhat ridiculous, others impossible and the specifications now agreed upon remedy this and other evils. Large buyers, such as railroads having international interests, now base their requirements on these specifications.

* * * *

Any reference to the present year's record in Machinery hall would be incomplete without comparative statement, and in this connection Enoch Cronk, who has been exhibiting machinery for the A. R. Williams Co., for the past sixteen years, seems competent to speak from experience. Mr. Cronk declares this to be one of the best years on record in the matter of prospects and also in business closed. While the enquiry was chiefly for light equipment, so far as metal working machinery was concerned, the interest in woodworking machinery was most encouraging and is indicative of the activity in the building and allied fields. The list of prospects shows that saw tables and woodworkers capable of multiple operations had quite a decided call, and there were several calls for small lathes. The general tone was far better than that of last year, and there seemed to be a larger number of people actually interested in making purchases if not immediately, then in the near future. In Mr. Cronk's opinion, the Fair as a barometer, indicated better times ahead.

News From the Welding Field

Mechanical Control of Oxy-Acetylene Torch

Cutting Metal by This Process Approaches Very Closely the Maximum Theoretical Efficiency—Obtaining Any Desired Shape by Means of Templates—Application of the Radiograph

By FRED J. MAEURER

DRAWINGS are reproduced in cutting by the No. 1-A oxygraph one half size, ratio of movement of tracing wheel and the torch tip (measured from center to center), is as one-to-two. Inasmuch as the kerf cut out with the torch is of appreciable width from 1/16 to 3/16 inch or more, it is necessary to make allowance for the kerf when cutting.

Allowance for the kerf may be made by adjusting the pointers so that the distance between the points and the center of the tracing wheel is equal to the width of the kerf. The preferable method is to make the allowance on the drawing, however. Track lines are traced on the drawing inside and outside of the pattern at the required distance to allow for the kerf. The tracing wheel is run directly on the line and the pointer is ignored except when turning a corner. It is then used to indicate when the point is reached at which the swivel should turn. When the oxygraph is used for production cutting, pencil drawing may be replaced by metal templates that serve as guides to the feed disc, and thus make it possible to reproduce the required shape exactly and as many times as desired. The construction of these templates depends on the shape desired and the allowable cost. When many pieces of the same shape are to be cut the cost of the templates will be distributed over the whole lot and a construction may be advisable that would not be used where only a few pieces are to be cut.

The simplest form of template is a grooved track for straight line cutting. This guide may be made from a strip of cold rolled steel, say 2 inches wide, ½ inch thick in which a vee groove ⅛ inch deep and about 3/16 wide has been planed in the middle. Such a guide is indispensable for cutting off and other miscellaneous straight line cutting where a smooth effect is desired.

When the oxygraph is required to cut circles or circular arcs it may be set up with the radius attachments provided which make the tracer wheels follow the arc automatically. The center point on the radius rod may be adjusted to any length of radius within limits. The radius rod is inserted in the tracer wheel bearing in place of the regular short pivot and thus the wheel is held tangent to the curve.

The work table of the No. 1-A oxygraph is 36 inches square and the area covered by the torch, following the largest drawing spread on the table, is 18 inches square. The largest rectangular cuts are made on the diagonal from opposite corners. Thus, a shape 2⅛ inches wide, 23 inches long can be cut using a drawing outline 4¼ inches wide and 46 inches long to guide the tracer wheel.

The oxygraph has a wide application and many uses in tool shops, manufacturing plants, locomotive works, shipyards, drop forging concerns and wherever tools, dies, forgings and shapes are produced. The cutting action of the torch flame is smooth and rapid, and as any shape can be cut, it is comparable to a metal band saw of great power, following straight lines, curves, and angles acute or obtuse. Thin sections are cut more rapidly, of course.

Punches, dies, stripper plates and bolsters are cut in tool shops with the oxygraph with resultant large savings of time and cost. The usual practice in making a cutting or trimming a die is to plane the block on the top and bottom, bevel the sides, lay out and drill holes to the line, cut out the walls between the drilled holes with a broach or drift and finish with hammer, chisel and file, or by backing out with a shaper or slotter. Almost invariably a die made in this manner warps and twists in the process which requires either replaning on the bottom or shimming up in the bolster. The removal of the mass of steel in the center of the die relieves internal stress and lets the block warp out of shape. Not so when the rough die block is cut out on the oxygraph. All troubles of this sort are eliminated and the danger of cracking in hardening is reduced to a minimum.

When the opening has been cut, the die (still hot) is placed in an annealing box, covered and left to cool. When cold it is planed and finished in the usual manner with the assurance that internal stresses have been relieved. Finishing the die to precise dimensions and backing out for clearance is done in the usual manner. Not only is the oxygraph useful for blocking out dies but it may be used also to cut the stripper plates and bolsters.

In the cutting of die steel, we have found through long experience that with all dies with a carbon content of above .75, pre-heating before cutting is absolutely necessary to insure a smooth accurate cut. All die steels below this carbon content can be cut without preheating. This necessitates the taking of the die away from the jig after it is lined up, preheated to about 750 deg. F. or over and then it is put back in jig and cut. On Fig. 9 you will note that two 6 inch I beams are set on the frame of the machine, to support the die. Two 1½ angles are then clamped to the I-beams to hold die in place. The shape to be cut is scribed on die and a little off the line of cut a 3/16 inch hole is drilled for starting. Two straight lines are also scribed both ways, through the middle of die which enables the operator to set his drawing in the correct position. As this die is set up in jig when cold, then taken off and heated and placed back on jig to be cut, it is necessary to make provisions for the difference in size of die due to expansion caused by preheating. To overcome this a few strips of newspapers are placed between the angle irons and die when it is first set up, and the die is cold. When the piece to be cut is taken off the machine to be heated, the pieces of paper are removed from jig and hot die put back again to be cut. Experience quickly teaches us how much allowance it is necessary to make for various sizes and thicknesses of dies.

Fig. 10 shows the cutting of twelve pieces of ¼ inch steel plates, one piece being laid upon the other, at the same time, on the 1-A oxygraph. You will note the drawing is laid out on the tracing table and is twice the size as the pieces to be cut. Fig. 11 shows a line drawing of this cut and will give a much better idea of the irregular forms that can be cut on this type of machine. These pieces were used for wheelbarrow construction.

The No. 2 oxygraph, designed for heavy forge work and large plates has two pantagraphs connected by a hori-

This material was prepared by the author, who is engineer of Airco-Davis-Bournonville Co., for the American Welding Society. The first part appeared in June 29 issue and the second in July 13 issue.

zontal square tubular bar in front that holds the torch or torches, also the driving motor and feed gear.

Fig. 12 shows the cutting of quadruple punch machine plates that were previously cut with the radiagraph. These plates are 1½ inches thick and total amount of linear feet of cutting is 15, and were cut at the speed of 13 inches per minute. This also shows how the No. 2 oxygraph increases production without adding labor cost, as the two plates were being cut at the same time with one operator.

Make Foreman Responsible for Safety of Men Under His Charge

THAT periodic instruction should be given to foremen and mechanics by competent instructors was the suggestion made by a Toronto coroner's jury in their verdict on the death of a mechanic while at work on a snowplow in the railway yards. The evidence indicated that the only instructions received by car helpers in the mechanism and air systems on railway rolling stock were from those experienced men with whom they work. In this case an experienced workman was struck on the back of the neck, the blow of a lever breaking it. He had overhauled three snowplows previously, and had turned the petcock letting out the air from the reservoir which supplied the wing controls, and the air brakes, but had started to work before all the air had escaped, with the result that when he knocked out the pin from a chain that held the lever in place it flew forward, striking him and jamming his head against a pipe behind him.

Verdicts upon fatalities of this kind repeatedly suggest the question, Who should be responsible for the safety of employees under such conditions as described? A phase of this problem is being discussed this week at the Eleventh Annual Congress of the National Safety Council in Detroit. Adam Wilkinson, labor commissioner of the American Writing Paper Co., Holyoke, Mass., dealing with the subject, "The foreman and his responsibility for employees under his supervision," said:—

"Much has been said about the foreman's responsibility for the safety of employees under his supervision. The strategic position occupied by the foreman makes it possible for him to exercise a great deal of influence in the field of accident prevention.

"It is not too much to say, however, that the management generally in years gone by, has not expected the foreman to assume any great amount of responsibility for the safety of employees in his department. To maintain a uniform output of standard product has in most cases been the chief function of the foreman, and when this was secured his services were generally considered satisfactory.

"The safety movement is comparatively new, as is evidenced by the fact that this is the eleventh annual conference of the National Safety Council. Whatever great accomplishments have been made in this brief period of time have merely taken us from the field of propaganda into the field of practical accomplishments. In the paper-making industry it required a long term of service before men are promoted to the position of foreman, and it is safe to say that the majority of men occupying these positions to-day have done so for more than a decade past, and before the days when the term 'Safety first' had any real meaning.

Not Propaganda

"It is unfortunate, but nevertheless true, that many of our foremen to-day regard the safety movement as propaganda, and when men regard this work as such they naturally feel they have performed their full duty when a uniform output of standard product is maintained in their department.

"What I have said heretofore is largely a review of the conditions that have governed the foremen in the past, and to assume a critical attitude of the things that have been done or the things we fail to do will get us nowhere in our endeavors to prevent industrial accidents.

"With a full understanding of the foreman's duties as he has conceived them to be in the past we can approach the question of securing the wholehearted co-operation of the foreman in our effort to prevent accidents in the future. Many progressive concerns that have made a careful study of industrial accidents have concentrated their efforts for safety work through the medium of the foreman.

"Recognizing as we do the important part the foreman plays in accident prevention it becomes necessary for the person who directs safety work to maintain a close personal contact with the foreman. The interest displayed by the foreman will largely be reflected by the attitude of the employees under his supervision. To overlook the foreman in any plan for safety work will result in much wasted effort. The foreman is the leader in his department, and no movement will advance very far without leadership. To make the foreman a leader in the safety movement should be one of the chief aims of the safety director. To bring the foreman to a full realization of his responsibility for the safety of employees under his supervision he must realize that any effort made to prevent accidents is not a side line, but one of his chief duties. Our safety creed for the foreman should be:

"1. The foreman should see that every employee is properly instructed how to do his work in a safe manner.

"2. The foreman should maintain discipline in his department, and prevent 'horse-play' on the part of the employees.

"3. The foreman should advise the superintendent of any unsafe condition that exists in his department.

"4. The foreman should be as much interested in the safety of the employees as he is in the quality of the product of his department."

PROGRESS MADE FOR NEW MACHINERY HALL

The increasing need for a new machinery hall or engineering building on the grounds of the Canadian National Exhibition was additionally emphasized at a meeting held in the Administration building on Sept. 5. The gathering was well represented by machinery dealers and manufacturers and the plans and specifications were discussed at some length. The directors of the Exhibition and machinery men in general realize that the existing machinery hall has outlived its usefulness as an adequate place for mechanical exhibits. It was announced that already upwards of 16,000 sq. ft. had been disposed of to firms anxious to acquire space in the proposed new hall. It was stated, however, that about 35,000 sq. ft. would require to be sold on a ten-year basis before the proposal to erect a new building could be taken up with the city council. It was felt that the necessary space could easily be disposed of provided some satisfactory arrangement could be made in regard to power rates and other charges not included in the contract for space. The plans under discussion called for an outlay of approximately $350,000 and it was thought that this building would take care of the engineering needs for many years to come.

It was announced that quite a number of English firms would willingly take large space once they were assured of a suitable building to exhibit their various lines. While nothing definite was decided at the meeting the proposition was favorably received by those present and at the close of the exhibition a general meeting will be held to go more fully into the matter. It is anticipated that a thorough canvass of those interested will bring in sufficient space contracts to make the new building an assured fact for 1924 at the latest.

Lathe tools, drills and cutters made of high speed steel, that have been burned in grinding, or skin softened, generally can be redeemed by grinding off 1/64 in. to 1/32 in. of the burned section. On account of the skin softening effect it is necessary to use softer wheels for dry grinding than for wet grinding.

Recent Developments in Mechanical World

Casting Shells Centrifugally

A PHILADELPHIA consulting engineer, Mr. N. Lilienberg, maintains that the sleeves to be shrunk over the explosion chamber of a field or siege gun can be cast vertically by centrifugal force satisfactorily and more cheaply than by the present elaborate process. He states that projectiles can be made centrifugally, about as good as forged, and the cavity closely conforms to the required construction. All projectiles, whether cast or forged, have to be machined to exact finish. The great advantage is the forming of the cavity, thereby saving the tremendous labor of carving out the hollows cold from forged solid blanks by using a great number of machines. It would be interesting to fill a rotating mould so completely that no cavity can be formed, and to ascertain the effect of the centrifugal force by the microstructure. The most difficult metal is low carbon steel to be thus treated. The work with other metals is comparatively easier.

Inspection By Micro-Photograph

PICTURES which look like bird's-eye views of a dish of scrambled eggs turn out to be photographs of tiny metallic surfaces, magnified a hundred times. They are the best object lesson the welder can find, for they take him down to the heart of the weld and show him that things are going on which he cannot possibly see with the naked eye. Surfaces which appear to be closed turn out to be full of small cracks and metal which he thinks is clean is discovered to be fairly peppered with impurities. The microscope backs up the instruction book at every step, showing in a convincing manner the results of good and bad welding practice, the effects of heat treating and hammering, and the nature of the metal at any desired spot. It tells the welder more about his work, in fact, than he can learn with the same degree of certainty from any other source. It doesn't lie; it is more apt to reveal falsehoods.

Improved Testing of Welded Parts

TESTING welds by electrical and magnetic apparatus has recently been accomplished on a small scale, with a probability that such apparatus can be improved and further developed to the point where such tests can be made to supplant the present-day destruction tests. A device which would enable an inspector to test the entire length of a weld without injury to the parts would put welding on an entirely new footing. Attempts are being made, states the London Metal Bulletin, to perfect such a device, and such attempts deserve encouragement. The only real test available at present is the service test, because tests on specimens are not positive indication of what the total welded production is worth. X-ray Testing is another possibility of great promise which has not so far progressed beyond the laboratory stage. The latter method, by the way, seems to have received more attention abroad than in America.

French Import Duty on Zinc

THE FRENCH government proposes to impose an import duty on zinc, which would consist of a minimum tariff to be increased by co-efficients. The minimum scale suggested is 4 francs per 100 kilos for raw, and 8 francs for rolled metal. Belgian producers, says The London Metal Bulletin, have been getting somewhat apprehensive over the question, the impression in that country having been that the duty was to be 8 francs and 36 francs respectively; but in French quarters it is pointed out that Belgium will actually benefit when the new tariff is in force, for the reason that she alone will be granted the minimum, German zinc will have to pay four times the minimum, while America and Poland will probably be given an intermediate rate.

Cutting Micarta Gears and Pinions

MICARTA, a non-metallic material for gear and pinion application that can be advantageously substituted for untreated steel, cast iron, bronze, and all other materials used for gearing, has been developed by the Westinghouse Electric & Manufacturing Co. Micarta is self-sustaining and may be machined in the ordinary manner into gears and pinions of various standard and special types with standard tools and equipment. It is a laminated product of specially treated woven fabric. By means of the various processes through which it is passed, it acquires a homogeneous structure with physical properties that make it especially adapted to the manufacture of gears and pinions. This material was developed to meet the persistent demand for silent gear drives. In addition to silent operation, some of its distinctive features are that it is self-supporting; is not attacked by rodents and vermin; is not affected by water or oil, or by most acid and alkali solutions; can be kept in storage indefinitely without deterioration; is applicable to a great many special constructions where it is not possible to use other non-metallic material; and has a longer life than any other non-metallic material, often outlasting cast iron and brass.

Canadian Ore For Europe

IT IS SOMEWHAT interesting to know that twelve steamers are said to be engaged in exporting Wabana, Newfoundland, iron ore to Germany, and it is estimated that about three-quarters of a million tons will have been delivered by the end of the year. The source of information does not disclose the reasons for Germany's import of ore from such distance, subject to payment in English funds. The explanation may probably be found in difficult industrial conditions as they exist in Germany to-day, in restrictions placed upon her own resources by war settlements, or in the desire of certain smelters to secure quantities of high-grade hematite for specific purposes. The deposit at Wabana is said to be one of the richest yet discovered and one that might easily attract demand from world-wide sources.

Most countries where the steel industry has had marked development are importers of iron ore. British smelters are large dealers with Norway. Spanish ore has been shipped into United States and likewise to Britain. Ore from the Greek archipelago has found its way westward for the purposes of modern smelters.

When the history of ore and metal movements have been recorded, some strange reversals of trade conditions will be found to have developed since the pre-Roman days in Britain when Phoenician traders wandered overseas to acquire Cornish tin.

Practical Ideas From Practical Men

INCREASING RANGE OF DRILL PRESS STRAPS

By H. M.

From time to time the writer has taken notes of various drill press set ups whereby the usual straps and clamps have been made to serve in a rather unusual manner. Some of these methods are here collected and set down as examples showing how these common attachments can be used for many jobs which are ordinarily done in quite a different, but not always in such an efficient way. The different jobs shown are of a type commonly met with and therefore the simple methods used in each case will no doubt be interesting to many readers.

In Fig. 1 the double flat spring piece is to be drilled near the open end. Instead of using wood or other packing to take the thrust of the drill on the top ends of these pieces a strap A was held at the correct height by means of nuts on two bolts. This eliminated the necessity for knocking packing in or out of each piece as it was drilled and made a very solid fixture

Fig. 2 shows a coupling with the usual projecting flange required to be drilled with a circle of bolt holes. The thrust of the drill is taken by strap A fixed at the opposite side. This is not tightened on the work at all but merely adjusted, by means of the nuts, to hold the piece level. It will be seen that when the work is pushed against the bolts holding the strap A, this arrangement makes an efficient jig, as the work is revolved from hole to hole with the flange pressed against the bolts, so that there is no lost time lining up each punch mark with the drill.

Drilling a hole on an inclined surface is always an awkward job; almost impossible without supporting the drill in some way. The slides shown in Fig. 3 had to be drilled near the end for stop pins. The drill is here supported on the end of strap A, this having a V cut to receive the unsupported half of the drill. The strap A is adjusted and tightened in place by nuts on a stud, screwed into a tee nut a binding fit. The other end of the slide is clamped down in the usual manner.

The sprinkler pipe shown in Fig. 4 is generally considered a vee block job, but in this case the vee blocks were discarded and a couple of heel clamps A, used instead. They are bolted to the table with the heels upward and the pipe passed between as the row of sprinkler holes is drilled. To keep the holes upright a U clamp B is fastened at the end of the pipe with its ends touching the table. This work was performed quickly, the only stoppage being caused by the necessity for moving the U clamp back each time it reached the end of the table, but this required infinitely less time than the task of squinting along the pipe each time it is moved forward as is necessary when the pipe rests in loose V blocks.

A method of using straps at the edge of the table when long rods have to be drilled on the end is shown at Fig. 5. The heel clamp A is placed at the top and a straight strap B at the bottom. The end of the elongated slot in A is veed while the strap B has a hole spotted. Both clamps are adjusted to hold the rods vertical by keeping them close to the edge of the table by means of the heel clamp A and allowing the ends to rest in the spotted hole in B. In Fig. 6 is shown a heel clamp ground down to fit the table tee slot closely and furnished with a nut and screw in the elongated slot. This can be slipped into place in a moment and adjusted to the required thickness of material being drilled and forms a very effective guard for preventing this kind of stock flying round or riding up the drill as it breaks through.

HABIT OF SECRECY

By H. Hamilton

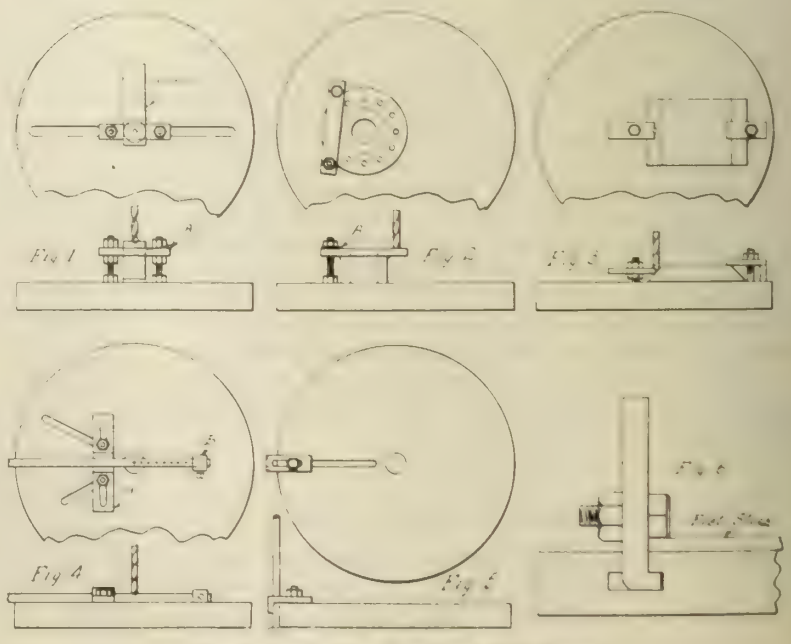
Nothing seems to be more prevalent with the human race than the habit of putting waste material in dark or secluded places, either for temporary or permanent abode. This is a condition far too common in the average industrial plant and one that requires considerable educational work in order to eliminate a source of danger that is seldom recognized as such by those participating in this practice. How often have we been walking along through the shop with a piece of useless paper, waste, wood, rag or other article and, when passing a box, bench, heating coil, or any convenient location, drop or throw the article out of sight. The next person may add his quota to the unseen pile, the accumulation making an ideal bed for the butt of a cigarette or the remains of an unburnt match. Of course, in the best regulated factories the non-smoking clause dispels the possibility of the cigarette or the match, but there is always a time when an exception to a rule proves disastrous. Aside from this the chance of spontaneous combustion is always present where rubbish is allowed to accumulate.

It is well to provide receptacles for placing waste and rubbish in, but if it is necessary to throw such material aside, cast it on the floor in the open where it can be swept up and removed. If you must expectorate while in the shop, do it in a cuspidor or on the floor in the open and not in a dark corner where it is hard to see and seldom cleaned. You owe it to your fellow worker, if not to yourself, to keep the place as sanitary and as free from the fire fiend as it is possible for you to do.

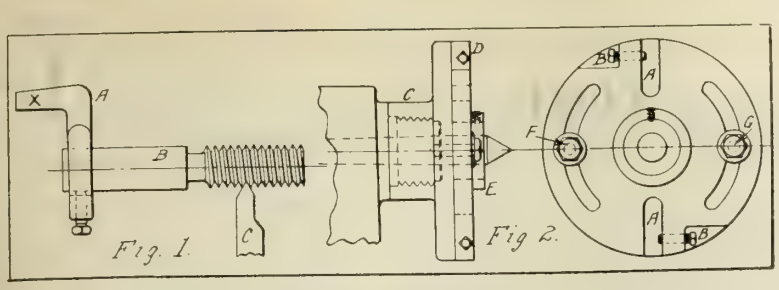
A LINE UP FACE PLATE

By F. Scriber

Oftentimes in metal working a rather difficult proposition presents itself where it is necessary to do some recutting on work previously machined. One such example is that of re-cutting oversized threads where the original thread must be accurately picked, that



Broader application of ordinary drill clamps.



A line-up face plate.

is to say, the tool must engage the thread in the same channel as previously cut when re-cutting.

This will be best understood by referring to Fig. 1 where A is a dog gripping a threaded stud B, C represents the threading tool. This piece of work B is placed in a lathe between centers in the usual manner for threading and the tool used and method of threading is the same as that usually employed except that a face plate such as is shown in Fig. 2 is employed to engage the tail X of the dog; this dog of course enters one of the slots A Fig. 2. The set screw B is set against the dog to hold it securely in place. This face plate is made in two sections C and D, C being screwed on the spindle nose of the lathe in the usual manner while D is revolvably mounted on C, being held thereto by a collar E and two set screws F and G. These screws go through an elongated slot in D into a tapped hole in C. The object of these elongated slots is to permit of swiveling the plate D relative to C which is permanently fixed on the spindle nose of the lathe.

In using this fixture the operator starts his lathe up in the usual manner, throws in his threading feed and advances his carriage sufficient to take the back-lash up. He then stops the lathe and with the cross feed runs the threading tool forward to see how it fits in the thread previously cut; as it is unlikely that the threading tool will match the previously cut thread he swivels plate until the tool will match the thread owing to the changing position of the helix of the thread caused by this revolving. When the thread and tool match the swivel plate, D is securely clamped in position and we are now ready to re-cut the thread. If it is desired to very accurately match a thread two or more trials are usually necessary to accomplish this and a piece of white paper placed beneath the threading tool may be used as a light reflector in matching the tool with the thread.

DRAWING THIN SHEET METAL

By H. James

In the construction of dies for the drawing of thin sheet metal difficulty is frequently experienced in obtaining a good draw without also securing a large percentage of split or spoiled work. This result is often traced to extra hard or brittle material and it is sometimes necessary to further anneal the stock before proceeding with the drawing operations. When the blank is large in relation to the diameter of the draw, it is usually advisable to relieve the outer portion slightly so that only 3/16 or ¼ in. around the die opening has a bearing on the blank holder. In addition to this the draw will be easier if the surface is stoned (radially) with a very fine stone or piece of fine abrasive cloth, carrying the process over the rounding edge of the hole. Better results are obtained when the corner has the shape of the broad side of an ellipse rather than a true quarter arc of a circle.

AN EMERGENCY FUEL

As an emergency fuel, a mixture of fuel oil with fine coal in as large proportions as the coal will absorb and hold is suggested by the United States Bureau of Mines to steam coal users and gas manufacturers to augment their fuel supply during the present shortage.

Slack coal that has a high percentage through an 8-mesh screen, or which may be crushed to sizes of one-eighth inch or less, will take up in oil from 30 to 40 per cent. of its own weight and make a fuel high in calorific value. Coarse, slack coal, however, as judged by a representative sample from the Pittsburgh market, will absorb oil to only 3 to 10 per cent. of its own weight, which would give a fuel having only about 4 to 15 per cent. increased heating value. The finer the size of the coal, therefore, the larger is the amount of oil which will be held. Tests made by the Bureau of Mines at its Pittsburgh experiment station indicate that the mixture can be made with either bituminous slack or anthracite culm.

This method bears a relationship to the Trent process of purifying coal by fine grinding and amalgamation with oil, now in operation at a plant at Alexandria, Va., which has demonstrated the success of a combination of oil and coal for steam-making, gas manufacturing and other fuel purposes. The present emergency proposal does not contemplate the cleaning process, but involves merely the simple mixing by shovel or concrete mixer. The Trent Corporation has volunteered to assist the government in advising in the use or application of oil-coal mixtures, and to waive during this emergency any claim of infringement of its process which may or may not be involved by the simple mixing of fuel oil and coal, without reference to cleaning.

An oil refinery at Baltimore, it is reported, mixed by shovel a ton of heavy Mexican fuel oil with two or three tons of western Maryland slack coal, and used it successfully in a switch engine. At the experiment station of the Bureau of Mines at Pittsburgh, it was found that mixtures containing one ton of Mexican fuel oil and four to five tons of Pittsburgh slack coal could be used in a hand-fired furnace.

In using oil-coal mixtures, the fire will smoke badly after firing, or while breaking up the coke bed from time to time. From such limited amount of testing as has been done by the Bureau of Mines, it was shown that careful firing is required to prevent continuous smoking. Experimenting must be done in each case to determine the best method of firing.

Chain grates and certain other automatic stokers are probably well adapted to handle the oil-fuel mixture if the bin and feeding devices are suitable. Oil-fuel mixtures will not fire spontaneously, but undoubtedly care should be exercised to ventilate bins where external heat may tend to drive off lighter gases, although the fuel oil which is on the market has had the lighter oils distilled from it.

Anthracite culm or dust which would sift through ordinary grate bars can be used successfully when mixed with the oil, as the oil causes it to adhere and the oil residue cokes as soon as heated. Oil and anthracite mixtures are not smokeless with hand-firing, the Bureau of Mines tests indicate.

This simple mixture of fuel oil and coal is proposed by the Bureau of Mines merely as a temporary measure. While under conditions of normal fuel supply such a mixture probably would not prove satisfactory unless it involved the cleaning feature embraced in the Trent process; in places where fuel oil is available it can be used to piece out a poor coal supply without the changes in equipment necessary to convert boilers to oil burning.

CANADIAN SHIPS TO CARRY COAL TO STATES

Victoria, B. C.—The Canadian Trading Company has chartered five steamships of the Canadian Government Merchant Marine to carry coal from Newcastle, N. S. W., to ports in the United States. The Canadian Trading Company has its head offices in Vancouver and this is the first time that a Canadian firm in British Columbia has chartered tonnage to carry coal to United States ports from another country. The steamships chartered are the Canadian Britisher, Canadian Highlander, Canadian Traveler, Canadian Transporter and Canadian Scottish, and they will carry lumber to Australia and return with coal for San Diego, San Francisco, Seattle and perhaps Honolulu.

New Things in Shop Equipment

UNIVERSAL GAUGING DEVICE

An attachment to be used in connection with a dial gauge, to provide accurate setting to any position or angle, has recently been developed. The device is particularly adapted to the testing of crankshafts, camshafts and valve stems; checking lifts of valves and valve cams; gauging thickness of piston rings, shims, bearing liners, piston diameters and recording the accuracy of flywheels and shafts. B. C. Ames Co., Waltham, Mass., are the manufacturers.

COMBINATION GRINDING ATTACHMENT

A grinding attachment that can be used in lathes as small as 10-in. swing has been placed on the market recently. The attachment is mounted on a special angle plate that is secured to the toolblock of the lathe, the motor and spindle being on opposite sides of the plate. The motor is pivoted to the angle plate, permitting movement for tightening the belt. There is a vertical adjustment to the spindle of 4 in., and the device can also be set at any angle in the horizontal plane and a reasonable angle vertically. Speed change is effected by transposing driving pulleys. Ball bearings are fitted to both wheel spindle and motor shaft. Spindle speeds range from 5,500 to 30,000 r.p.m. These tools are made by the United States Electrical Tool Co., Cincinnati, Ohio.

HAND PRESS AND PULLER

A combination hand press and puller especially intended for garage and jobbing shop service has recently been introduced to the trade. It is designed for the purpose of removing wheels, gears and bushings from shafts, and likewise for pressing similar parts in place. Three lag screws are provided for securing the base to the bench. The device can easily be converted into a serviceable arbor press for handling round pieces up to 18 in. in diameter. Three sizes of yokes provide for a wide range of service. The arms are reversible and may be used either side out and also at any spacing within the range of the tool. The parts are made of 40-point carbon steel and capable of withstanding a strain of 50,000 lbs. per sq. in. of sectional area. These tools are made by Geo. W. Dover, Providence, R.I.

HORIZONTAL HYDRAULIC PRESS

A hydraulic press capable of exerting a pressure of 25 tons at speeds ranging from ¼ to 6 in. per minute has been developed and placed on the market recently. The maximum speed of ram on outward stroke is 37 in. per minute, which speed is increased to 56 in. per minute on the return stroke. Ram speeds can be readily and instantly changed by a control lever located on top of pump. The pump is directly driven by a 2 h.p. motor and no accumulator or auxiliary pump is used. Relief valves are provided to prevent damage should ram be driven against stop at full speed. Initial pressure of 800 lbs. per sq. in. are used on a 9 in. piston. The ram has a stroke of 30 in. It is claimed that the press operates without shock or pulsations. These presses are built by the Oilgear Co., Milwaukee, Wis.

HAND AND BENCH VISE

A combined hand and bench vise, especially designed for toolmakers, patternmakers and others, required to work on small pieces that cannot conveniently be held in the hand, has been placed on the market. The tool is made of semi-steel and in two sections. The anvil clamp is secured to bench or other support and the vise portion is located in a tapered dovetail slot on the front of the clamp. No setscrews or other fastenings are required. The jaws of the vise are kept always parallel by means of a pantograph arrangement beneath the vise screw. This device permits the work to be lifted from position without removing from the vise. Either plain or serrated jaws are supplied with the vise. The Malleable Iron Fittings Co., Brantford, Conn., are the manufacturers.

GRINDING WHEEL DRESSER

A grinding-wheel dresser in which the tool-steel discs are carried on roller bearings has recently been offered to the trade. One of the advantages is the easy running and long life of the spindle. A ¾ in. stud carries a cage holding the rollers of the bearing, which in turn support a bushing on which the cutters are securely fastened. The bearing is practically dust-proof but ample means are provided for oiling. The cutters are made of corrugated steel with an outside diameter of 2⅜ in. The body is so designed that it can be held in a tool post or on a magnetic chuck. When used on the chuck the tool rests on an inclined face, so that the flat surface and the heel of the shank are both in contact with the face of chuck. These tools are made by the Desmond-Stephan Manufacturing Co., Urbana, Ohio.

INSPECTION GAGE AND STAND

An inspection gage and stand, especially intended for facilitating the calibration of accurate internal diameters in hardened and ground work, has been placed on the market recently. The gage is a modification of the internal micrometer and is adjusted by means of a micrometer screw and sliding wedge, the under surface of which is inclined at an angle of 15 deg. to the body of the tool. The amplification of movement provides very fine increments of diameter. The graduations permit of variations as small as .0001 in. It is stated that these measurements can be estimated as easily and as accurately as on the .001 divisions on the standard micrometer. The stand holds the tool firmly and allows the inspector to slide the work upon the measuring surface without fear of injuring the finish, a tapered hardened ring permitting of free entrance of the work. The operator handles the work in his left hand while making adjustments with his right. The gripping surfaces of the stand are faced with soft metal to protect the finished parts of the tool. These tools are made by John Bath & Co., Worcester, Mass.

SPECIAL MICROMETER

An interesting design of micrometer has just been placed on the market. The frame and barrel is in one piece, the U portion being of oval section. Provision is made for compensating the wear of the thread. The adjustment of diameter is made by the spring nut adjacent to the barrel. The thimble is pressed over the sleeve of the measuring spindle and it is also split and provided with a knurled ring nut for clamping it to the sleeve. The tool may be dis-assembled, adjusted and put together again in a few seconds. After completing the adjustment the spindle is moved into contact with the anvil, and the thimble adjusted to zero, after which the ring nut is tightened and the micrometer is ready for use. These tools have been brought out by the Central Tool Co., Auburn R. I.

POLISHING AND BUFFING LATHE

A new line of ball-bearing polishing and buffing machine has recently been introduced to the trade. The machine is of the duplex type, being equipped with two independent spindles, the wheels being carried at the outer ends. The spindles are operated separately and either spindle, together with the respective bearings, can be removed without disturbing the alignment. The bearing housings are of the ball and socket type. The spindles may be driven either by overhead or underneath shafts, facilities being provided for placing a motor in the base of the frame. Each spindle has a length of 32 in. The overall length of two spindles is 66 in. Spindles have a diameter of 2 in. Floor space required 26 x 42 in. The No. 5 machine has a net weight of 950 lbs. They are made by The Mitchell Engineering Co., Springfield, Ohio.

PORTABLE SAW BENCH

A small portable saw bench for the general use of pattern makers and in jobbing shops has recently been placed on the market. The machine is self-contained, the saw arbor being driven from a motor mounted on a bracket at the side of the pedestal, the belt running inside the column. The table has a working area of 16½ by 21½ in. and is fixed at a height of 38 in. from the floor. It is provided with a rip fence that may be set at any angle for bevel sawing, as well as a cut-off slide adjustable to mitre cutting up to 45 deg. The arbor runs at a speed of 2,400 r.p.m. and carries a 6-in. saw. The table may be tilted to any desired angle and may be swung clear when changing saws. The machine weighs 184 lbs. It is made by A. C. Sisson, of Pawtucket, R.I.

ANTI-EXPANSION CENTRES

A new type of centre for use in lathes and grinding machines has been developed and placed on the market recently. A series of helical grooves are milled in the shank proper which has a longitudinal movement within the outside tapered shell. This motion is opposed to a very stiff adjustable coil spring. The object of this construction is to take care of the expansion of the work, caused by the heat generated by the cutting of the metal, thus allowing the centre to recede and prevent binding. Lubrication of the interior is possible through a hole in the adjusting screw.

The same firm has produced anti-friction centre, the inner spindle of which revolves with the work, a forward radial and rear thrust bearing being mounted in the outside casing. The outside of shell is made with Morse tapers but other tapers may be secured when desired. When used for grinding machines the centre heads are reduced in size to permit the wheel to pass over end of work. These centres are made by the Snellex Manufacturing Co., Rochester, N. Y.

ELEVATING PLATFORM TRUCK

An electric elevating platform truck especially designed for the handling of large core racks into and out of core ovens, has been placed on the market recently. The battery compartment is provided with removable end plates and with rails for guiding and holding the storage battery trays. The motor is flexibly connected to the elevating mechanism by means of double worm reduction. Four crankshafts, two at each end, are connected to the worms by means of bevel gears. Hardened steel rollers on the crankshafts bear on hardened steel plates on the underside of platform. All four crankshafts operate simultaneously when platform is being raised or lowered. Limit switches are provided for platform travel. A contracting-type shoe brake is interlocked with the treadle, so arranged that the brake is applied when foot pressure is completely removed. Three operating speeds are provided for each direction. The maximum speed of truck is 700 ft. per min., on rubber tired wheels 27¾ in. dia. The load carrying wheels are 10¾ in. in dia. and are mounted on double-row ball bearings, with a ball thrust bearing fitted to facilitate steering. The platform is 7 ft. 2½ in. long and 30 in. wide, and 11½ in. from the floor in the low position. The truck can be turned completely in a 12-ft. radius. These trucks are made by the Atlas Car and Manufacturing Co., Cleveland, Ohio.

PROFILING AND MILLING MACHINE

A new design of profiling and milling machine has been developed and placed on the market. The work table has a working surface of 30 x 16 in., with a throat in the column that provides extra accommodation for wide work, the maximum distance from spindle to back of throat being 14 in. The table has a traverse of 12 in., and a cross movement of 7 in. The knee has an adjustment of 6 in. while the spindle has a vertical movement of 2¾ in., the latter being derived from rack and pinion. By means of helical gears the cross-feed of the table can be conveniently operated, owing to the fact that traverse and cross-feed handles are in the same plane. Provision is made for operating the cross-feed direct by means of a crank handle. The tool spindle is hollow and bored for No. 3 Morse taper. The spindle is supported in three bronze bearings, the drive operating through bevel gears from cone pulleys on the end of a horizontal shaft. The machine requires a floor space of 36 x 45 in. and is manufactured by the Robbins Machine Co., of Worcester, Mass.

DOUBLE-ENDED AUTOMATIC THREADING MACHINE

An automatic machine having two heads and especially adapted to high-speed threading has recently been placed on the market. The machine is capable of threading both ends of a forged or rolled stay bolt simultaneously, and both threads are in line and continuous lead. The condition of the intermediate portion of the bolt does not affect the accuracy of the thread alignment.

The machine is provided with a hopper that has a capacity for about 55 minutes of operation. A work-feeding mechanism with a pair of floating jaws holds the staybolt and presents it to the dies so that both ends are in exact alignment. The large lead screw is fitted with long bronze nuts, and suitable cams are provided for operating the various parts automatically. The spindles are connected to the main driving shaft by means of gears. The camshaft change gears regulate the speed of the camshaft to conform to the different length of threads to be cut. When the die heads are just clear of the work, the work-holding jaws open and move backwards, ejecting the finished staybolt. The mechanism then operates to place a rough bolt in position. To assure continuous lead the machine is accurately set by means of a master staybolt or long-thread gage, which is inserted in the dieheads. One die is closed on the thread and the second head is adjusted so that the die closes perfectly on the thread at the desired point. The machine is provided with a safety shearing pin which prevents damage should a rough blank be too much out of shape. The machine has a capacity to thread staybolts up to 1 15/16 in. dia. and from 7 to 18 in. long. Five machines can be operated by one man as it is only necessary to keep the magazines filled. These machines are manufactured by the Cleveland Automatic Machine Co., Cleveland, Ohio.

SCREW AND NUT SETTING TOOLS

A line of portable and stationary electric driven tools for the rapid setting of screws, studs and nuts, has recently been offered to the trade. The portable equipment represents in general outline an electric drill and may be operated from an ordinary light socket. The stationary design is intended to be operated from a power line. The motor of the stationary tool is universal under the same current conditions that govern the motor in the portable tool. The motors are of the high speed type, the spindles operating at a 10 to 1 reduction. The driving mechanism consists of a multiple-disc clutch, adjustable for any torque within the capacity of the motor, and driving a positive clutch through a splined shaft. When the disc clutch is fully released the automatic kick out permits the removal and replacement of tools while motor is running at full speed. It is stated that the slip clutch insures all screws and nuts being driven to the same tension and that prevents shocks to the motor. This tool cannot be overloaded. During the actual setting of screws the speed is reduced to 350 r.p.m. The possibility of crossed threads is eliminated as nuts are held with their axes in line with the operating spindle. The stationary tool handles nuts from ½ in. to 1 in. These tools are the product of the Elecdrive Manufacturing Co., of Syracuse, N.Y.

CATALOGUE

The Canadian Ingersoll-Rand Co., of Sherbrooke, Que., have just issued a new catalogue covering their complete lines of engineering equipment. The book is prepared in a very convenient and interesting style, being subdivided into fifteen sections, fourteen of which are devoted to some particular class of product and the last portion to a general collection of tables, formulae, etc., for the service and reference of engineers. The catalogue is compiled in loose-leaf card index form, permitting the removal or addition of certain pages or sections when necessary. The book contains 230 pages held together in an expansion cover by means of brass screws. Three hundred halftone cuts are used to illustrate the various lines.

Coal for U. S. in Canadian Ships

SETTLEMENT of the coal strike seems to have added some intensity to the complacency with which the general fuel outlook is now regarded. What with supplies on hand and deliveries that should dribble through, the impression is that the country should be able to worry along until something like normal conditions return. It may be a tendency of the times, or of the holiday season at least, to discourage the development of a serious problem by assuming an attitude of indifference. At no time did the much-abused dealer seem to worry about it, and he did his share to reassure the public that everything would be all right and that consumers would be well looked after. Ottawa has had not only an eye but its hand on the situation but naturally not to the same extent as the man who had an empty coal bin, a family of several kids and prospect of a cold Canadian winter. Advice has been plentiful but apart from making it unanimous that there was a coal shortage and that consumers should acquire what substitutes they could, nothing of a practical character has developed.

Municipalities with foresight have made an attempt to buy Welsh coal and considerable tonnage is now on the way. This will help some. In the meantime, a correspondent in Victoria, B. C., advises us that a trading company there has chartered five steamers of the Canadian Government Merchant Marine to carry coal from Newcastle, N.S.W., to ports in the United States. This, it is said, is the first time a Canadian firm in British Columbia has chartered tonnage to carry coal to the United States from another country. This may be regarded either as neighborly or as good business, or both. It may mean that Canadian ships could not be profitably employed in carrying coal to Canada; it may mean that Canadians were needlessly alarmed over prospects of a coal shortage; it may mean, further, that a record, showing Canadian ships earning money on outside service, would look better at the end of the fiscal year than would Canadian ships employed in carrying coal for Canadian purposes. All of these things may look well, but they do not obscure the somewhat peculiar picture of Canadian ships employed in rushing return cargoes of coal to the United States, the base of this country's coal supplies, where scores of ships are standing idle that could be used in the coal business. Some person seems to be awake to the fact, on the other side, that even with coal strikes settled, there is going to be a shortage and that supplies will have to be supplemented from outside sources. Such enterprise is entitled to everything it can get.

Of course, on the other hand, it may be argued that these ships are restricted to Pacific service and that it would hardly be worth while to transfer them while there seems to be as many bottoms as necessary to meet the emergency. But on a cold winter day, Canadians may not easily reconcile themselves to the somewhat anomalous proposition.

Something Tangible at Last

EXHIBITORS in Machinery Hall at Toronto National Exhibition this year fully expect that the project of a new engineering building will be proceeded with at once. Plans have reached that stage where something tangible is at last emerging and committees now have something to work on. In another part of this paper will be found a report of a meeting at which manufacturers discussed the proposition. As compared with conditions in the old building, what is offered in the new structure on the price basis proposed, must appeal as being adequate and reasonable. Good display spaces, proper moving and shipping facilities, lighting that will show goods at their best, consideration of demonstrating requirements, including the all-important adjunct of electric power at minimum rates, are matters that will receive careful attention. There must be a representative display, and further, it must be a creditable one. The object of such a building should be to develop an annual event that will bring out the best in engineering enterprises. This result has been attained in other buildings in which industries have been segregated at the exhibition. Manufacturers of machinery are in a position to make a showing that should be the outstanding feature. The question of location is hardly as important as some would think. A building such as proposed is attractive because of the general impression created by its display.

Ready for Freight Congestion?

STEEL companies report remarkable activity among the American railroads in the building of new rolling equipment. Immense tonnages of steel are being consumed in this work, yet there exists considerable doubt as to whether there will be anything like adequate facilities to handle the quantities of coal, manufactured articles and food products accumulating for transportation. Canadian roads are doing very little in this matter of car construction, even with a bumper wheat crop in sight. It is pointed out that for all immediate purposes the rolling stock on hand is sufficient. The situation in the United States, however, will have its effect on Canadian deliveries and the coming winter may see another hopeless congestion at international points. Available supply of cars will be affected by the protracted railway shopmen's strike, yet against this is the declaration by road operators that they will be in good shape for the emergency, while the government, by issuing priority orders, is attempting something to prevent tie-up. Food for human consumption receives first consideration; then feed for livestock; then livestock, perishable products, coal, coke, fuel and last, all other commodities. The phase that will be followed with considerable interest is that which concerns industry in general and the necessity that it be well served under these circumstances. The situation will demand efficient handling.

Production Increases but Deliveries Difficult

Coal, Pig Iron and Steel Ingots Show Improvement—Now Up to the Railroads—Business in Steel Centres Handicapped—Canadian Furnaces Restricted to Light Output—Bars and Sheets Advance Though Demand Continues Good

LARGE IMPORT TONNAGE SHOWS BROAD ACTIVITY

DECLINING continuously in the past two months, the low point in pig iron and ingot production was reached at the end of August with respective records of forty-five and fifty per cent. of capacity. This is the latest Pittsburgh advice. There has been a subsequent increase in production, as several mills in Pittsburgh district, the valleys and about Chicago have resumed operations. Of these plants, practically all had by-product coke ovens. Coal shipments, generally, will be severely limited by railroad congestion, however, and nothing can be taken for granted as to increasing production in coal or iron and steel industries. Offerings of pig iron in Canadian markets are confined to restricted output as scarcity of coal has made operation on a large scale impossible. Production for August will show very low levels indeed, with no improvement in sight Algoma spot price is $39.30, while the Steel Company is out of the market for new business. Some Scotch pig iron has made its appearance, but not in such large quantities as to be a factor in relieving marked scarcity should such develop.

August has been a good month with the dealers in the iron and steel business, as a whole. In some quarters it is reported that while the volume was large, it was not due so much to the number of orders as to the size, while other dealers declare that orders showed unusual number. Structural material has been an outstanding factor, but large importing interests state that their bookings represent considerable variety. A $350,000 month by one concern, with an advance from $165 to $170 in the basic price, was considered a remarkably good showing for August. Still it is predicted the price peak has not been reached and even in the more conservative quarters advances are being seriously considered. For example, an advance of five cents in steel and iron bars represents unanimity in $3.40 as the maximum figure. Sheets continue to be a feature in the demand and prices show slight advances. Galvanized, No. 28, are quoted at $6.75; blue annealed, No. 10, at $4.50 and black, No. 28, at $5.50. The market continues fairly strong for finished products. An advance has been announced in wood screws, the new discounts being, for flat head, bright, 80-5% off; flat head, brass, 75-5% off; flat head bronze, 70-5% off; with ovals and rounds ranging from two to three per cent. below these figures.

Advances have taken effect in boiler tubes and then there appears to be some difference between the Montreal and Toronto quotations. In the former, on a three-inch lapweld, the latest figure is $28.50 per 100 feet, while Toronto quotes $27.50; on four-inch the Montreal price is $42, Toronto, $39. On standard butt and lapweld pipe, the price remains firm, raw materials are very slow in shipment and coupled with this is the gradual increase to about $8 per ton for skelp.

Demand is such that advances are being made an inevitable factor under present circumstances and there is little indication as yet that a conservative attitude is developing. The feeling is that with a shipping congestion in sight it would hardly be wise to curtail when the purpose has any urgency.

Montreal reports improvement in the scrap metal market, owing to continued scarcity of pig iron. Summerlee Scotch iron is the only kind available on that market at present and the stock is limited. Business generally is inclined to be spotty, some houses reporting improvement and others claim that the volume is not up to the mark. Quotations on steel are firm and supplies are increasingly difficult. Quotations are such as to restrict operations of Canadian mills. Demand for machine tools continues very light although supplies are keeping up.

Toronto

September 13, 1922

AUGUST has come through with a fairly good record so far as business booked by dealers is concerned. Advancing prices have not resulted in curtailment and this fact is taken as evidence that there is considerable urgent work in process. Import tonnages have been large, indicating wide industrial variety, and represent a slight improvement in transportation. This is the big problem at the present time, and some apprehension is felt with regard to the attitude of shopmen of the Canadian railroads. A tie-up of shipping would mean little short of industrial paralysis.

In pig iron markets there is little activity and is confined almost entirely to rush business on small lots. Algoma is operating on a limited scale quoting $39.30 spot. Foundries seem to be fairly well covered for the time being. It is a situation in which little if any help can be forthcoming from American furnaces. Report comes from Buffalo that imported iron, particularly in the East, has affected the demand for the domestic article. Summerlee Scotch pig has become quite a factor in Quebec, but has not yet made its appearance in Western Ontario, where it would be at an obvious disadvantage in competition.

Scrap metal markets remain somewhat inactive. There are quantities of heavy melting steel in sight but it is firmly held in anticipation of higher prices. Dealers' quotations of $11 per gross ton, Toronto, are in line with the $16.50 to $17.00 Buffalo figures. No. 1 machine cast iron is quoted at $18, Toronto; machine shop bearings at $6 and malleable scrap at $11. Local prices follow:

Copper, light, per 100 lbs.	9 00
Copper, crucible	11 50
Copper, heavy	11 25
Copper Wire	11 25
No. 1 compositon	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 25
Light brass	4 50
Medium brass	6 00
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton.	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine castiron	18 00
Pipe, wrought	7 00

Iron and steel bars, once more, appear slated for an advance to the maximum of $3.40 indicated in these columns for some time. Sheets also show the result of the upward swing in the American markets and the demand continues strong. Black sheets, No. 28, are quoted at $5.50, Toronto, and galvanized sheets at $6.75. Folowing is the local list as revised:

Iron bars	3 35	3 40
Steel bars	3 35	3 40
Reinforcing bars	3 35	3 40
Steel hoops		4 50
Tire Steel		3 50
Spring steel	7 00	14 00
Band steel, No. 10 gauge and 3-16 in base		3 90
Small shapes		3 40
Sheets, black, No. 28		5 50
Sheets, blue ann., No. 10		4 50
Canada plates, dull 52 sheets		5 75
Canada plates, all bright		6 75
Galvanized Sheets, No. 28		6 75

Non-ferrous markets have been practically featureless for the past week and no price movements of any importance are reported. The market for copper products continues to show strength. Manufacturers declare that deliveries are an increasingly difficult factor. Non-ferrous metals are quoted locally as follows:

Lake copper	17 75
Electrolytic copper	17 50
Castings, copper	17 00
Tin	37 00
Spelter	8 00
Lead	8 00
Antimony	8 50
Aluminum	21 00

Machine tool markets continue to show quite a fair demand for woodworking

equipment. From representatives at Toronto exhibition came the report that considerable interest was shown in small metal working lathes and machine tool accessories and supplies.

New discounts were issued recently by the Steel Company on wood screws. These are now as follows: Flat head bright, 80-5%; oval head bright, 77½-5%; round head bright, 77½-5%; flat head brass, 75-5%; oval head brass, 72½-5%; round head brass, 72½-5%; flat head bronze, 70-5%; oval head bronze, 67½-5%; round head bronze, 67½-5%, f. o. b. Hamilton, Toronto and Montreal with freight equalized thereon. Terms, 2% cash, 30 days.

Montreal

September 13

LOCAL jobbers are not of one opinion regarding the amount of business moving at present. Some houses appear to be handling an increase in business, and others claim the volume for the past week has dropped off. This condition is only to be expected, on account of the national disturbance in the iron, steel and coal industries, in addition to a partial tie-up of the transportation systems. Steel is becoming more difficult to procure each week, and the quotations are decidedly firm. Some mills have closed down entirely owing to the coal shortage and small bookings. Canadian pig iron is off the market temporarily, that is to say no new orders are being accepted, but business already booked is being taken care of. Machine tools are quiet. But little change has taken place in the non-ferrous metal market during the week. The scrap metal market has improved slightly.

Iron and Steel.—Mill quotations on steel are $2.60 base and $2.70 base, to the large consumer, and the jobber respectively. The tonnage moving continues to be about the same, but the jobbers are experiencing greater difficulty each week in maintaining warehouse stocks. The Algoma Steel Corporation have completed the 48,000 ton rail order for the C. P. R. and have practically closed their mills. Only a portion of the mills of the Steel Company are operating. The mills operating are producing small steel products largely, thus the tonnage produced is not large. Local jobbers are at present depending on local mills such as the Peck Rolling Mills and the Canadian Tube and Iron Co. for their supplies. These mills are kept reasonably busy supplying the local jobbers and consumers. Galvanized sheets, also blue annealed and black sheets are greatly in demand. Merchant bars, structural sections, and heavy material are very quiet. Boiler tubes are moving considerably better this week. Quotations on them have advanced during the week. Small steel products have continued to move satisfactorily. The local quotations are as follows:

Iron bars, base	3 15 to	3 25
Steel bars, base	3 15 to	3 25
Reinforcing bars, base	3 15 to	3 25
Steel hoops	4 25	
Tire steel	3 25 to	3 40
Spring steel	7 00	
Band steel, No. 10 gauge and 3-16" base	3 65	3 75
Small shapes	....	3 40
Sheets, black, No. 28	....	4 40
Sheets, blue ann., No. 10	....	4 05
Canada plates, dull, 52 sheets	....	5 50
Canada Plates, all bright	....	7 00
Galvanized Sheets, No. 28	....	6 50

Pig Iron.—Practically all Canadian iron is off the market temporarily, inso-far as new orders are concerned. The nominal quotation is $40.80, but no business is being done at this figure. Practically the only iron available at the moment is Summerlee, and this stock is limited. It is expected that Carron iron will be offered at an early date. The consumption of the foundries at this time is only nominal. Most firms bought heavily some weeks ago and the producers are protecting their customers who placed orders well in advance. Thus there is very little actual demand for iron, and the amount that does exist is being handled with the Scotch iron. The local quotations are as follows:

Algoma, No. 1, car lots on tracks, nominal quotation	40 80	....
Summerlee, 5-ton lots, warehouse	38 50	33 50
Summerlee, 30-ton lots, dock	33 50	....
Carron, 30 ton lots	33 50	....
Do., 5 ton lots, ex. warehouse	38 50	....

Machine Tools and Shop Supplies.—No improvement is shown in the machine tool line. The recent labor troubles have accentuated an already bad situation. Only a few sales of small tools have been reported. The supply business is holding its own. Machine shops are not taking on additional men and consequently the volume of business in this line shows only nominal improvement. Price levels are being maintained reasonably well. In a few instances an advance is quoted owing to the increasing costs of materials.

Non-Ferrous Metals.—For the past week the non-ferrous metal market has been unusually quiet. No price changes have been made, and the volume of business remains about the same. Orders continue to be for small lots but are well distributed throughout the province. The list of local quotations is as follows:

Lake Copper	17 75
Electrolytic Copper	17 50
Castings, Copper	17 25
Tin	35 50
Lead	7 00
Spelter	8 75
Antimony	6 25
Aluminum	22 00

Scrap Metals.—Owing to the continued scarcity of pig iron, the demand for all kinds of scrap, particularly for No. 1 heavy machine, has improved. The demand for non-ferrous scrap has also shown a little more activity. In a few lines quotations have advanced. Throughout the province the market appears to be awakening. Up to the present quite a reasonable amount of business in iron and steel scrap has been done. Local quotations are as follows:

Copper, light per 100 lbs.	9 00
Copper, crucible	11 50
Copper, heavy	11 25
Copper Wire	11 25
No. 1 composition	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 25
Light brass	4 50
Medium brass	6 00
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine cast iron	20 00
Pipe, wrought	7 00
Car wheels	17 00
Steel Axles	15 00
Machine shop turnings	4 00
Stove plate	16 00
Cast boring	4 00

Pittsburg

September 13

THE LOW point in pig iron and steel production was reached just at the end of August, since when there has been an upward swing. At the low point, pig iron production was at the rate of about 20,000,000 tons a year or say 45 per cent. of capacity, and steel ingot production at about 26,000,000 tons a year, or say 50 per cent. of capacity. Production declined continuously during July and August. Average rates of production during August were about 21,500,000 tons a year in pig iron and 30,000,000 tons a year in steel ingots.

All told, about a dozen steel works blast furnaces have resumed operations since the end of August, in the Pittsburgh district, the valleys and the Chicago district. These resumptions were almost wholly at plants having by-product coke ovens, to which coal began to move rather promptly after the signing of wage scales with the United Mine Workers by various operators. There has been little if any resumption of blast furnaces tributary to the Connellsville coke region. The strike in the region did not end with the posting of the high wage scale by various operators on August 22 and 23, the men holding out for actual union recognition. Production of coal and coke in the region has increased slightly, by men drifting back to work and by men being brought into the region, just as was the case before the advance of between 40 and 50 per cent. in wages. Now, however, the strike, although apparently formidable, can hardly be considered a commercial factor, since careful study indicates that the limit of transportation from the region has been reached and if there were labor to produce more coal the additional tonnage could not be moved.

A fair guess probably is that while the production of steel was at about 50 per cent. of capacity at the end of August it is now, or will be within a few days, at 55 per cent. It would be quite unsafe, however, to conclude that a rate of improvement has been established. Coal production has been increasing rapidly, but on all hands it has been predicted that railroad congestion would develop and would severely limit coal shipments for months. Coal production, once it reaches a certain rate, may not stay there but may decline, the particular point being that there may have been many idle coal cars near mines and it is no trick to load them the first time

while it may be difficult to get them to destination and back again for a second loading. The trade's view, therefore, is that nothing should be taken for granted as to increasing coal production or, in turn, increasing pig iron and steel production. While no precise predictions are made, it is commonly considered quite unlikely that, at any time in the remainder of the year, the steel industry will operate at the best rate previously attained this year, between 70 and 75 per cent. of capacity, late in June.

Pig Iron Not Helped.—A feature of the increased pig iron production seen thus far is that it is practically confined to the steel interests, those that have by-product ovens. The great majority of merchant furnaces in the north depend either upon Connellsville coke or upon surplus coke offered from by-product ovens, and there is practically no improvement in coke supplies from these sources.

Offerings of pig iron are very limited indeed. They are of iron now in stock or certain soon to be made. There is no disposition to negotiate for pig iron to be made by furnaces now idle, when they may chance to resume. Small lots of Bessemer iron have sold at $34, valley, an advance of $2 in the week. Basic iron presents no market. Some in the trade call it "not under $30, valley." Some is said to be offered at $32 or $33. Steel works are not in the market and it is problematical what they would pay. Very likely none would be willing to pay as much as $30. The steel producers would take a loss using iron at such a price, on acount of prices at which they owe steel to customers. Some small lots of off basic are said to have sold at around $33, for malleable foundry use, but this is no criterion of the basic iron market, since purchases, if made, would represent substitution for standard malleable, which would cost more.

Foundry iron for Pittsburgh delivery is on a Buffalo basis, the nearest point of regular supply, the Buffalo market, being $34, furnace, making, with $3.28, $37.28 delivered Pittsburgh, equivalent to $35.51 at valley furnaces as the valley-Pittsburgh rate is $1.77. It is said that some small resale lots have gone at $35 to $36, valley basis.

Steel Market Strong.—On the whole, finished steel products have been distinctly inactive in the open market in the past week. No particular significance is attached to the fact that there was little incentive to trading. All mills appear reluctant to sell. Some are already sold far ahead and do not care to increase their obligations, while buyers would not be interested in such late deliveries. Mills that can make relatively early deliveries hope they can get higher prices later and are anxious to get as high prices as possible, not merely to make money, but to equalize on some sales on which they will have a loss. Steel sold a few months ago, at prices then going, means a loss to make now as costs are so much higher, with high coal costs and with wages up 20 per cent. all around.

The minimum on bars is 1.90c and on shapes and plates $2, but these prices seem to be made only by the Carnegie Steel Company, for delivery at mill convenience. Moderately early deliveries are held at 2.25c in case of all three products, and that is the real market. Plates for shipment in two or three weeks command about 2.50c.

Additional sheet mills have advanced asking prices, and there is a wide range. It is a question whether any independents will sell on the Steel Corporation's basis of 3.35c for common black, while asking prices range up to 3.75c, depending on delivery, etc. Buying at premiums has been light.

Rivets have been advanced $7 a ton, to 3.00c for button head structural rivets and 3.10c for cone head boiler rivets.

Sheet bars have sold in several instances at $40, and the $38 price that figured recently has disappeared. Slabs are regarded as nominally at the same level. Billets might possibly be picked up at $38. In the first three months of the year sheet bars were $29 and the present sheet bar market insures a continuance of sheet prices at about the present range while it suggests that tin plate may advance above $4.75, which has been the nominal market since late in the old year, but which has been shaded almost continuously by independents.

The Steel Corporation's unfilled obligations increase by 173,944 tons during August, to 5,950,105 tons, against an increase of 140,630 tons in July. The August increase represented 12 per cent. of the month's capacity, and as shipments were at about 67 per cent. of capacity the bookings were about 79 per cent., comparing with 86 per cent. in July and 103 per cent. in June.

The Flint Varnish and Color Works, Toronto, are in the market for the following machinery:

1 Hoefer 21in. drilling machine with wheel and lever and geared power feed, automatic stop and back gears. 1 Walcott 16in. high duty crank shaper cone drive, complete with 10in. swivel vise, counter shaft and wrenches. 1 McDougall 18in. x 30in. x 12ft. gap lathe with 3-step cone, double back gears and quick change gears and complete with compound rest, steady rest, follow rest, large and small face plates, necessary wrenches and two speed friction counter shaft. 1 12in. Cushman geared scroll chuck, 3 jaw fitted. 1 16in. Imperial 4-jaw independent chuck fitted. 1 Power hacksaw back geared on leg base backed geared. Lowest f. o. b. price, Toronto, is required.

In the malleable fitting list, there has been a revision of discounts. The discount to dealers of 70 and 5 off. has been superseded by a discount of 70 per cent. covering class A and of 60 per cent. on classes B and C.

KEEPING THE INDUSTRIAL PLANT FIT TO WORK IN

(Continued from Page 19)

is if he felt he had several grievances constantly. A clean, well lighted and well ventilated shop inspires a man to do better work. He will develop a pride in his accomplishments and will endeavor to conduct himself so as to be in harmony with his surroundings, with an idea of meriting promotion.

A shop that is kept in A-1 condition always suggests prosperity, and all men prefer to be identified with successful concerns, as they usually mean steady jobs with good rates of pay. Perhaps these suggestions may be described as being idealistic, but nevertheless, they are very concrete factors in our industrial world, and the sooner employers of labor realize the truth of this doctrine, the sooner will dawn the day when industrial controversies, strikes, lock-outs, etc., will be conspicuous by their absence. No great or permanent change was ever made in a day. Such changes must be made slowly. It should be the aim of employers to encourage labor to sink prejudices, and to freely discuss, through accredited representatives, any ideas that labor may have as to the improvement of their condition. Everyone grants that labor should have the right to earn a wage that permits of a good standard of living. Labor must come to believe that employers are sincere in their attitude toward them, and when this is accomplished, we will have gone a long way toward establishing a permanent industrial peace.

SUBSTITUTE FOR IRON PIPE

A cheap bituminous clay pipe, to be used in the place of cast iron pipe, has been devised by the Carnegie Institute of Technology, states the Industrial Digest. The new form of piping, it is expected, will be as satisfactory for drainage and sewerage purposes as the more expensive cast iron pipe which has been the only variety available up to the present.

The chief difficulty in the search for a substitute for cast iron has been to find a method of joining the ends of the substitute piping without leakage. Various bituminous cements were recommended for this purpose but early experiments showed that they were unable to overcome the difficulty. An entirely new joining technique in the use of these cements has now been devised. Four important points have been established: (1) the joining of the pipe can be effectively accomplished by the use of a proper bituminous compound; (2) the joints made in this manner will withstand any pressure that the pipe itself will stand; (3) a pipe line, joined in this manner, can be thrown out of alignment without causing leakage at the joints; (4) leaks due to poor workmanship can be repaired easily and quickly.

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

PIG IRON

News From the Industrial Field

Montreal.—Quebec has made an additional grant of $500,000 for the maintenance of roads.

British Train Traders Ltd., are sending an exhibition train carrying samples of British goods across Canada, leaving Montreal the end of October. The tour will take ten months. Two hundred and ten British manufacturers will exhibit their goods.

Henry Ford's decision to close his plants Sept. 16 may be rescinded if shipments of 250 tons a day from a coal corporation in the south is up to specification and requirements. It is stated that one of Ford's representatives had authorized shipment.

Montreal.—Authorized capital of $33,997,200 is reported by companies incorporated during the past week. Dominion incorporations totalled $31,165,000; Alberta, $126,000; British Columbia, $650,000; Ontario, $1,460,000; Prince Edward Island, $5,000; and Quebec, $577,200.

Ocean Falls, B. C.—Pulp was shipped during the week to Stockton, California, this being the first consignment of pulp to that destination, all previous shipments going to Astoria. A full cargo of paper was also sent to San Francisco in addition to which a cargo was loaded for Australia.

Sherbrooke, Que.—The latest concern to secure a site in Sherbrooke with a view to establishing a plant is the Canadian Brakeshoe Company, and it is predicted extensive developments will soon be under way. Industrially, Sherbrooke has experienced improved conditions this summer and immediate prospects are bright.

Mission, British Columbia.—It is reported that placer gold and platinum sands have been found on the Fraser River. Favorable assays have encouraged prospectors who intend to develop them on a large scale. The location of the deposits is not more than 125 miles from the coast.

Ottawa.—Every man in Canada who wants work can get it according to managers of labor bureaux who are advertising for men. There is plenty of work, it is claimed, and more jobs than there are applicants for them. The majority of vacant positions is for laborers, though the situation regarding skilled labor is stated to be brighter.

Haileybury, Ont.—Operations have commenced at the new mill of the Temiskaming Pulp and Paper Company, recently erected at a cost of approximately $1,000,000. The plant will have a daily production of forty tons of ground wood pulp, which will be shipped to Chicago, Kalamazoo, and points in the state of New York.

No one can purchase a ton of hard coal in New England without buying a ton of soft coal, according to a recent regulation in prospect of fuel shortage. There is reported to be a frantic demand for hard coal all along the Atlantic seaboard and there is very little anthracite on the market.

Solution of the unemployment problem, by importing all the farm labor that could be secured is advocated by Ontario Boards of Trade. Increased population in this way would also cause a brisker demand for manufactured goods and it is felt that an aggressive advertising campaign by the government is necessary. Steps will be further considered at a meeting of Associated Boards of Trade in Owen Sound, Sept. 21.

Recent changes on the operating staff of the C. P. R. include the promotion of W. B. Howard, district passenger agent at Toronto, to the position of assistant-general passenger agent at Montreal. W. Fulton succeeds Mr. Howard at Toronto, and W. Horner will assume the duties of assistant district passenger agent at Toronto.

Anyox, B. C.—The Granby Consolidated Mining and Smelting Company's plant is reported to have broken all records in production in July, producing more than three million pounds of copper matte during the month, the best previous record being approximately 2,800,000 pounds. The company has 1,400 tons of copper matte at Vancouver loading for the New Jersey refinery. It contains $408,000 worth of copper; $88,000 worth of silver; and $72,000 worth of gold.

Montreal.—It is reported that a large manufacturing plant, costing approximately $1,000,000, will be erected soon by the Dominion Glass Company in the vicinity of Montreal. The company now operates two plants in Montreal, but it is understood that the proposal is to erect one large plant which will not only look after the business now being handled by these two plants, but will also provide for any expansion of the company's business.

Official announcement indicates that the output at the Leaside plant of the Durant Motors of Canada will aggregate nearly 40,000 cars, 25,000 of these being the new Star model. The two large buildings now under construction will be completed by the close of the present year and production of cars and trucks will gradually increase to a rate exceeding 1,000 a month. It is expected that the electric units and axles for the cars and Mason trucks will be manufactured at Leaside by March of next year.

Montreal.—H. S. Campbell, travelling representative of the D. F. Jones Manufacturing Co., Ltd., states that business is improving in his line. On January first the factory warehouse at Gananoque had a stack of thirteen thousand dozen shovels. To-day the stock in the same factory warehouse is reduced to three thousand dozen, and the factory has been working 150 men full time for some time past. The company had a very fair year in 1921, but the figures for this year promise to be as great as those of any previous year in the history of the business, which was established in 1852.

At the annual session of the British Association recently held in Hull, Que., it was decided to hold the meeting for 1924 in Toronto. Next year's session will take place in Liverpool. During the 91 years that the Association has been in existence Canada has had but three meetings. Annual sessions are always held in some leading place throughout the Empire. The main branches of science dealt with by the association are mathematics and physics (with which are associated astronomy and meterology, chemistry, geology, geography, zoology, physiology, botany, economics and statistics, education, engineering, anthropology, psychology and agriculture).

The Ford-Smith Machine Co., Hamilton, Ont., have just completed a special hosiery press, which is the first of its kind made in Canada. This machine is of single bed construction 50 x 40 ins., and hosiery forms are placed between the bed, and pressed by steam at about 30 lbs. pressure. They are making other presses of similar design, also larger styles of 3-bed construction. The smallest size being made weighs approximately 3,100 lbs., while the three-bed press being made is of two sizes, 50 x 40 in., and 78 x 42 in., weighing approximately 4,500 and 7,000 lbs. respectively. The Ford-Smith Co., have been going in for special machinery to a large extent lately, having made attachments for hosiery machinery, special millers etc., etc.

Montreal.—In the proposed new city hall, on which construction will begin this autumn, there will be no tower, but an additional storey, and it is planned to have a flat roof. The Quebec legislature has granted the city authority to spend $1,500,000 in this connection.

Montreal.—Vernon G. Hardy has been appointed manager of the new Mount Royal Hotel in this city. This hotel is stated to be the largest hotel in the British Empire and one of the largest in the world. Mr. Hardy is a Canadian, being a native of Galt, Ontario.

Montreal.—Judgment was handed down on Sept. 6th by the Dominion wreck commissioners in the case of the collision between the French steamer "Indochine" and the Danish steamer "Sarmatia," which occurred on August 11th last. Thiok weather on account of fog and the nuisance from fumes and smoke in the vicinity of Three Rivers were largely blamed. The inquiry set these conditions aside and placed the responsibility with the officers and pilot of the 'Indochine."

Montreal. — The Canadian Pacific Steamships Ltd steamer "Monteagle," withdrawn from the service to the Orient recently when the larger Empresses were placed on that route, has been chartered to carry a cargo of two and a half million feet of lumber from Vancouver to Montreal for the harbor commissioners. This is the first shipment of lumber to leave Vancouver this month. The voyage, it is estimated, will last thirty-two days.

A Pittsburgh correspondent suggests that, in meeting the pending coal shortage, consumers should pass up anthracite entirely and use a combination of bituminous and coke. He points out that there is little anthracite used now in the big centres of Pennsylvania, and that for years there has been a growing tendency in the Central West to use coke as a substitute for anthracite or as an improvement on bituminous. In Central Ontario last year, anthracite sold at $15.50. This winter it is predicted the price will range from $10 to $20. Belleville dealers are offered coal at $25 a ton.

Montreal.—Two local munition plants belonging to the United States Government were placed on sale recently. The Lachine plant went at $32,700. This property was assessed at $118,755. The purchaser was S. W. Narizzano, managing director of the Saxonia Fruit Preserving Co. It was announced after the sale by the purchasers, that they would extend their operations so as to make use of the newly acquired property.

The other property was located in Longue Pointe. The bidding for this reached the figure of $292,500, and no higher bids could be obtained. This bid was rejected, and the plant is still for sale. The cost of the plant was in excess of $1 500,000.

Quebec.—Steel and concrete construction on the extension of the Chateau Frontenac is being pushed by the Dominion Bridge Co. Twelve stories of steel and concrete have been erected on the tower and eight more, including a roof space are to come. There are 475 engaged. The addition means 400 more rooms for the Chateau.

Canadian purchasing agents will hold their annual convention in Montreal, Oct. 7th. Among other features of the program, there will be a discussion on transportation, on the relationship between the purchasing agent and production department, and an hour to receive salesmen. It is proposed to have one or two members from each of the associations represented, introduce these subjects. The National executive will hold their fall meeting in Montreal at this time.

Montreal.—Work is again to be started on the new French-Canadian hospital at the corner of Sherbrooke St. East and Maisonneuve St., after it has been dormant for fifteen years. New plans are being prepared and it is estimated that the new hospital will cost $800,000. The corner stone will be laid on September 8th. Dr. L. de L. Harwood is president of the hospital, and Dr. O. F. Mercier is general superintendent, while Tancrede Bienvenu is treasurer.

Fort William, Ont.—Every effort possible is being made to have the N. M. Paterson Company one million bushel addition to its elevator ready for the handling of a good portion of the 1922 crop. Over 1,600 piles have been driven, some of them to a great depth, but all of them down to hard pan. Forty three new bins will be erected, each ninety feet, of varying capacity. When completed the total capacity of thi elevator will be 1,750,000 bushels.

Sydney, N. S.—Officials of the British Steel Corporation have announced that wage increases running from ten to fifteen per cent., and affecting all classes of workers at the steel plant, will become effective shortly. Approximately 2,800 men are affected by the new order. The new schedule will include a general levelling-up of rates in different departments. The minimum rate, that paid for common labor, is increased from 24½ and 26 cents to 28 and 30 cents an hour. A detailed statement of all rates has not yet been worked out.

An active campaign has been started by the Grimsby Chamber of Commerce to stimulate the industrial interests of the smaller towns in Ontario. The initial move was made last week when about 200 representative citizens from all parts of Ontario gathered at the King Edward Hotel at Toronto to discuss plans and organize the various districts. It has been decided that a representative of the Grimsby body will tour the province and address other Chambers of Commerce on the course of action that is to be pursued.

Dodds Canadian Iron Works, Welland, has been incorporated with capital stock of $250,000 to engage in the iron and steel business as converters also as coke producers and manufacturers of milling equipment.

Sudbury, Ont.—After a suspension of eighteen months the statement that the International Nickel plant at Coppercliff has again resumed active operations with a staff of 650 men, will be good news to the district. As capacity production has not yet been considered, preference has been given to pre-war employees and the majority of these are now engaged on an eight-hour shift. Regular shipments of the matte will be made to the refinery at Port Colborne, where all of the refining will be done hereafter, the refinery at Bayonne, N. J., having been scrapped. The refined nickel will be shipped to the new $2,000,000 rolling mills at Huntington, Va., where it will be rolled into malleable metal and marketed mostly in the United States.

Contracts for the rebuilding of a number of locomotives have been received by the Canadian Locomotive Company, Kingston. At a meeting of directors recently it was pointed out that prospects for business were very much improved and that, if conditions continued favorable, further contracts should soon be obtained. The works will probably open in a month's time with 100 hands, to be increased as activities develop. The company has declared a regular dividend of 7 per cent. on the preferred and one per cent. on common as against 2 per cent. formerly. Last year the company received no orders for locomotives and only a few orders for repairs. It was therefore necessary to meet current and interest charges, etc., out of income from investments which was insufficient. The net loss for the year was $191,351, but interest on investments and adjustment of valuation of investments reduced the deficit to $76 299.

Professional engineers of British Columbia protest that they have poor recognition in big undertakings. Recently a Prof. J. G. Kerry, Toronto and McGill, was chosen by the city to report on a hydro project. Local engineers were not notified, and naturally felt that, being on the ground, they were more conversant than an outsider. The city took the stand that any eligible engineer in the province might have personal interests. This was an inference and the engineers protested further. They pointed out that the city did not have to go outside to get a magistrate. At a recent meeting engineer after engineer arose and reported he had been brought to the province to undertake some big engineering works. He had completed it satisfactorily, and had been so pleased with British Columbia that he had stayed. Since then he had received no big jobs. It was decided to appoint a committee to appear before the mayor and council and request that the association of Professional Engineers in the province be considered in future.

SIMONDS
HACK SAW
BLADES

Hack Saw Machines equipped with Simonds Blades produce more work at a minimum of expense. These blades cut rapidly, hold their cutting edge longer and do not shell teeth.

They are made of special steel and heat treated by an exclusively Simonds method to bring out the utmost in cutting efficiency and lasting qualities.

LABOR LOST 700 YEARS

There were 22 strikes in progress during July involving more lost time than in June, 1922, or July of last year. Some 15,736 workmen were involved and the estimated time loss was 261,240 working days, equivalent to more than seven hundred years, as compared with 25 strikes, involving 10,155 workpeople and 251,134 working days in June, 1922; and 41 strikes, 9,413 workpeople and 92,891 working days in July, 1921. On July 1, there were on record 19 strikes, affecting 5,045 workpeople. Three strikes were reported as having commenced during July as compared with six during June. Two of the strikes commencing prior to July and one of those commencing during July terminated during the month, leaving 19 strikes involving about 9,726 workpeople on record at the beginning of August.

The general movement in prices noted by the Department of Labor, was slight, both the index number of wholesale prices and the retail prices of foods showing little change from June levels, though with an upward tendency.

The index number of wholesale prices stood at 225.3 in July as compared with 224.3 in June; 238.6 in July last year; 346.8 in July, 1920; 294.0 in July, 1919; 248.7 in July, 1917; and 134.6 in July, 1914. The general decline in farm products and foods noted in June was continued in a lesser degree in July. Grains and livestock and meats again fell, but dairy products, fish, and miscellaneous foods showed an upward tendency. Most of the other groups were slightly higher. The chief increases for the month were in butter, sugar, raw wool, raw silk, jute, coke, linseed oil and turpentine with smaller increases in metals, gasoline, and coal oil. The chief declines were in grains, cattle and beef, sheep and dressed lamb, boots, some chemicals, glassware and crockery.

In retail prices the average cost of a weekly family budget of 29 staple foods in some 60 cities was $10.27 at the beginning of July; $10.18 for June; $10.97 for July, 1921; $16.84 for July, 1920; $11.62 for July, 1917; and $7.42 for July, 1914. The total for food, fuel, and rent averaged $20.67 for July, as compared with $20.58 for June; $21.53 for July, 1921; $26.92 for July, 1920; $18.41 for July, 1917, and $14.17 for July, 1914. In food no violent changes occurred; dairy products were practically unchanged, while mutton, flour, and potatoes were slightly lower. Nearly all the other items showed small increases, the chief of which were in beef, pork, and sugar. Fuel and rent were unchanged.

Following the posting of a notice in St. Thomas shops that a cut of seven cents an hour would go into effect at once and be retroactive to the time when the company first gave notice of a reduction, the men of the federated shop crafts employed by the Michigan Central left their benches for a conference. A board of conciliation to arbitrate such a dispute is necessary in Canada before a strike can be called and it is the report of this board in favor of reduction that is evidently behind the action of the railroad officials. The men are not bound by the report and are at liberty to strike. They voted, originally, 90 per cent. in favor of strike. About 400 men are affected in St. Thomas. The reductions amount to $8,500 a month. It is reported that the M. C. R. do not intend to enforce the retroactive measure against Canadian shopmen.

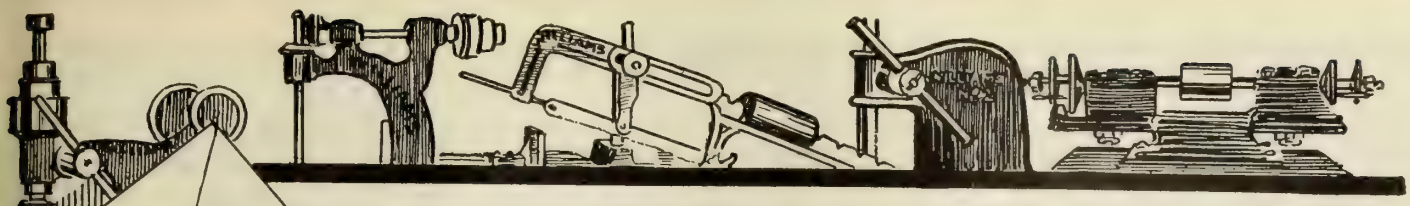
COMPLETING LARGE CONTRACTS

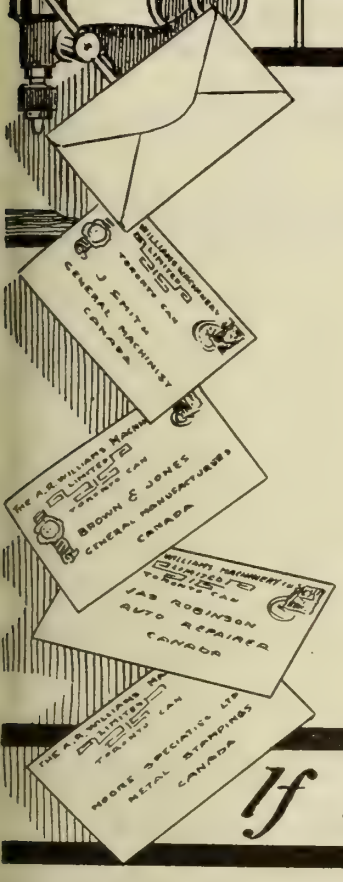
Industrial construction started this year in Fort William is fast nearing completion and several big jobs will be finished shortly. The Barnett and McQueen Construction Company have completed the two million bushel annex to the Northwestern elevator in the west end of the city, and in twenty days' time machinery will be installed and the new house turned over to its owners ready to commence handling its portion of the 1922 western grain crop.

A start has been made by the Fegles Construction Company in pouring the concrete for the tanks of the new annex to the N. M. Paterson Elevator Co., West Fort William, and it is expected that by September 20 they will be completed. The new addition will have a capacity of one million bushels and consists of a single unit of twenty-two concrete storage tanks. The Fegles Company expect to turn the house over to the Paterson Company, fully completed ready for the handling of grain, on October 15.

Another week will see the completion of the half-million-dollar steel conveyor bridge which has been under construction at the Island number one coal dock of the Canadian Pacific Railway since April 25 by the McMyler Interstate Construction Company, Cleveland, Ohio. The bridge is a huge affair built entirely of steel and equipped with electric motors which not only operate hoists contained thereon but serve to move the entire bridge from place to place at the will of the operator.

Rapid progress is being made with the erection of the paper mill adjoining the pulp manufacturing plant of the Fort William Paper Co., at the Mission. The new plant will consist of four main buildings and progress is exceptionally well advanced on each. One has already been roofed and it is expected that the roofs will be built over the other three by the end of the present month. It is the intention of the paper company's engineers, under whose supervision the plant is being built, to have all buildings completed by the time cold weather starts so that the installation of machinery can be carried on during the winter.





Make a Note of this Now

Sooner or later you will be needing a new Machine, Tool, or Supplies of some kind. When that time comes, your need may be urgent; you'll need intelligent service that can handle your order in the quickest time.

That is our specialty. Our huge stocks and our Service Policy ensure the filling of practically any order without the waste of a moment's time—it includes the Williams' Guarantee too. It's worth making a note of right now.

Our regular monthly Machinery List is full of bargains.

STEEL SASH COMPANY DOING BIG BUSINESS

WITH repeat orders coming in from Vancouver to Montreal for steel sash, J. E. Dennis, manager of Steel Sash Ltd., London, Ont., says there is every reason to believe that business in general is in a healthy condition. Mr. Dennis has practically closed a $3,000 order to supply steel sash for a large Toronto building and he expects to close one for $2,400 within the next few days. Large shipments have just been made to Vancouver and Montreal. The factory is working full time.

Chief among the large buildings which were supplied with steel sash by this London factory recently are the following: Public Utilities Building, Galt, Toronto Transportation Commission car barns, Hydro Electric buildings, Chippawa, Montreal Waterworks power house, Fletcher building, Victoria, B. C., the new Arcade, Vancouver, B. C., Eugene Phillips plant, Brockville, Ont.

BRITISH AND AMERICAN COAL OUTPUT

A comparison of American and British figures for coal production shows that the average mine worker in the United States produced more than 700 tons yearly while output in the United Kingdom is at present reported to be only about 223 tons per worker, states the Commerce Monthly for September.

A substantial increase in the productivity of British miners has been effected since the British coal strike of 1921. In 1913 the average annual output per worker employed was 258 gross tons; and in 1915 it was increased to 265 tons. Following that year, however, the average output dropped steadily until for the year 1920 it amounted to no more than 182 tons, but the current output of coal is reported to be at an annual rate of about 223 tons per worker. While this is still below the prewar rate, it represents a considerable increase over previous postwar years.

The average output per man in the United States is in striking contrast to that in the United Kingdom. The 1913 average, for the United States, was no less than 681 tons and it was steadily increased to 768 tons for the year 1918, declining to 743 tons in 1920, the latest available year.

This striking difference is due largely to the greater use of machine mining in the United States. Prior to the war less than 9 per cent. of British output was machine mined, against 43 per cent. for the United States. Since then there has been some increase in the use of machines in the United Kingdom, particularly in the Scottish fields, where about one-quarter of the output is now mined by machine. In the Welsh fields, however, only 2 per cent. of the output is machine mined.

The relatively limited use of machine methods in the United Kingdom is in part ascribed to hostility of the workers who fear displacement but in good measure it is said to be due to the physical characteristics of many British mines, which render the adoption of machine mining impractical or difficult.

FOR GREATER SAFETY

At the eleventh annual congress of the National Safety Council held recently in Detroit, the following resolution endorsing a safety platform for next year was adopted:

Whereas, the 80,000 accidental deaths and millions of injuries occurring each year on our streets, in our industries, in homes and elsewhere are a blot on American civilization and the cause of untold suffering and sorrow, and

Whereas, the direct economic cost of industrial accidents alone exceeds one billion dollars annually, and

Whereas, experience has demonstrated that at least 75 per cent. of industrial accidents are preventable and that approximately an equal reduction is possible as regards public accidents, therefore be it

Resolved: That the National Safety Council in its eleventh annual congress in Detroit assembled advocates:

1. The safeguarding of all dangerous machinery and places according to standard methods of proved value;

2. The development of industrial equipment and processes along lines of inherent safety for the double purpose of eliminating accident hazards and increasing production efficiency;

3. The education of all workmen and their supervisors in safe methods and habits of work;

4. The training in safety of all school children, as well as students in colleges and universities, both for their own protection and as an object lesson in good citizenship;

5. The adoption and strict enforcement of uniform, practicable laws and ordinances for the safeguarding of vehicular traffic and the protection of the multitude of law-abiding drivers and pedestrians against the thoughtlessness and recklessness of the few, and;

6. The mobilization of all community forces through state and city safety councils for securing those ends through the overwhelming force of enlightened public opinion.

Machinery to the value of over one million pounds sterling, of which more than one-half classed as "mining and accessory," was imported by Trinidad from United States and was probably all in connection with oil fields. In sugar machinery, the business has always been in the hands of manufacturers in the United Kingdom. Some attempt is being made to form a Canadian engineering alliance in Barbadoes in order to promote Canadian business. It is believed that a large field is being exploited there by American firms for certain kinds of machinery that could be equally supplied by Canada.

Ottawa.—There has been very little unemployment among machinists here, as the majority of local shops were able to keep their forces going on the following wages: Machinists, 50 hours per week, 56 cents per hour; moulders, 50 hours per week, 60 to 65 cents per hour; laborers, 50 hours per week, 40 cents per hour. The large majority of these trades in contract shops are non-union and preferred reduction in wages to shorter hours or lay-off. One concern recently secured a contract for about 200 tons of large castings and with one exception prices were so close that an increase of less than 5 per cent. in wages would have sent the work elsewhere. The city buys street castings, etc., at $2.95 per hundred pounds delivered as required.

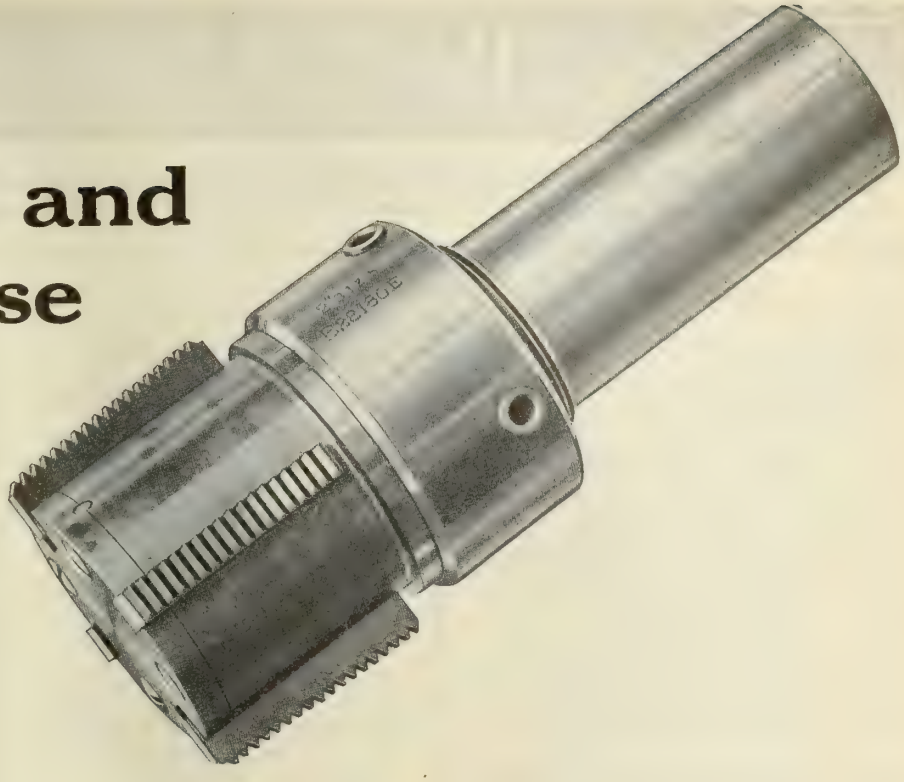
A Tap For Both Hand and Machine Use



Geometric Adjustable Non-Collapsible Tap

GEO MET RIC

Right on the Lead

A Threading Tool that is "making good" in the reduction of production costs—the Geometric Adjustable Non-Collapsible Tap.

It is especially valuable on machines having no means of closing a Collapsing Tap or for some other reason not permitting the use of a Collapsing Tap.

The Geometric Tap has the advantage of use either as a hand tap or as a machine tap.

The Tap is not equipped with the collapsing device, but has all the other advantages of a Collapsing Tap. Being adjustable, correct size is always maintained.

Chasers are readily removed for regrinding, and when finally necessary to renew the chasers, this can be done at slight cost. A great saving over renewing the entire tap.

Each size tap accommodates chasers for a range of diameters.

Reducing production costs is no new occupation for Geometric Screw Cutting Tools and Machines.

Let Us Prove It.

MODERN EQUIPPED FOUNDRY FOR RENT

A WELL KNOWN MANUFACTURing plant will rent their **UP-TO-DATE** foundry to responsible party. They will also take large proportion of foundry output.

The floor space in main foundry is approximately 140 feet by 60 feet, and building is well lighted and equipped with all modern facilities including 4-ton electric overhead crane, continuous elevated track, metal pouring crane, and compressed air lines at convenient points.

A 10-ton cupola in ideal central position is also installed, and in addition there is an up-to-date mill room with large tumbling barrels, sand blasting machine, etc., also a first class core room with good sized ovens. A well equipped pattern shop is also included.

This foundry is located in an ideal manufacturing district in Toronto, and has a railway siding right to the door. This is a chance of a lifetime and none but responsible parties need apply. For further particulars write Box No. 813, Canadian Machinery.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

BLACK & DECKER

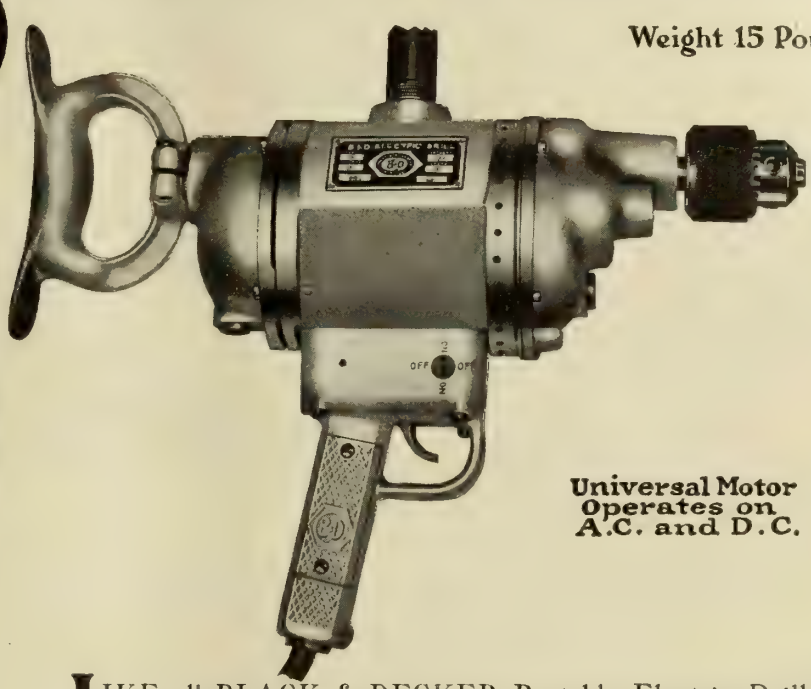
SPECIAL HALF-INCH DRILL

"With the Pistol Grip and Trigger Switch"

$106.00

1922 Model
1922 Price

Weight 15 Pounds



Universal Motor Operates on A.C. and D.C.

By removing two screws cover plate of switch handle may be lifted off, exposing terminal block to which electric cable and motor leads are attached by means of SCREW TERMINALS. Cable may be renewed quickly and easily without soldering.

A little thing which means a lot to the busy mechanic.

LIKE all BLACK & DECKER Portable Electric Drills this SPECIAL HALF-INCH DRILL is powerful, durable, comfortable to handle and perfectly controlled.

"The Pistol Grip and Trigger Switch" not only provides a large comfortable grip and instant control of the switch, but reduces the breakage of expensive drill bits, because the switch may be operated at critical times, such as when bit is breaking through the work, without disturbing the position of your hands. *"The Pistol Grip and Trigger Switch"* control is instinctive—practically automatic.

THE BLACK & DECKER SPECIAL HALF-INCH DRILL fits the BLACK & DECKER BENCH DRILL STAND, or POST DRILL STAND, and can be secured from your regular jobber.

SPECIFICATIONS

HOUSING—Aluminum Alloy.
MOTOR—Universal. Operates on Direct or Alternating Current.
AIR COOLED—Die Cast Aluminum Alloy fan keyed to armature shaft.
GEARS—Double Reduction, stub tooth, chrome nickel steel heat treated. Run in grease like an automobile transmission. (No brass gears are used on any Black & Decker tools).
CONTROL—*"With the Pistol Grip and Trigger Switch."* Improved switch handle with removable plate and screw terminals.
CHUCK—Three-jaw geared nut chuck for straight shank drills up to ½ inch.
NO LOAD SPEED—475 R. P. M.
NET WEIGHT—15 pounds.
EQUIPMENT—Drill is complete with 15 feet duplex electric cable, attachment plug, combination spade handle and breast plate, detachable side handle.

The fact that Canadian Industrials insist upon the finest tools and equipment obtainable makes BLACK & DECKER a natural choice.

MADE IN CANADA

A very substantial reduction in prices has been made possible by the establishment of our Canadian factory.

CREDIT

BLACK & DECKER National Credit Service enables any reliable person in Canada to purchase Black & Decker equipment from his jobber on terms that permit the equipment to pay for itself.

The Reason for .000,005" Accuracy

Every gage you use, whether it's a master, inspection or a working gage, is based on some standard of measurement. If this basis of measurement is a set of gage blocks, built-up to form various dimensions, the nearer those blocks individually are to absolute accuracy, the smaller the errors in the built-up stacks.

That's why Hoke gages are made and **guaranteed** accurate to within five-millionth of an inch. They give you a basis to work from that practically eliminates error at the start and ensures closest possible accuracy in your gages and in all the measuring you do with them.

Even though shop tolerances are usually to thousandths, gages set to Hoke block "millionth of an inch" accuracy are bound to be more accurate — and keep your work more accurate — than when set to other standards.

And remember this, Hoke Gages cost no more than other high-class gage blocks of less guaranteed accuracy. They are so reasonable in price that any shop can well afford a set. They're sold singly, too, or in sets of 5, 10, 34 and 81 blocks.

The Hoke Gage Catalogue should be in your reference library—it's yours for the asking.

To Holders of Five-Year 5½ per cent. Canada's Victory Bonds

Issued in 1917 and Maturing 1st December, 1922

CONVERSION PROPOSALS

THE MINISTER OF FINANCE offers to holders of these bonds who desire to continue their investment in Dominion of Canada securities the privilege of exchanging the maturing bonds for new bonds bearing 5½ per cent. interest, payable half yearly, of either of the following classes:—

(a) Five year bonds, dated 1st November, 1922, to mature 1st November, 1927.

(b) Ten year bonds, dated 1st November, 1922, to mature 1st November, 1932.

While the maturing bonds will carry interest to 1st December, 1922, the new bonds will commence to earn interest from 1st November, 1922, GIVING A BONUS OF A FULL MONTH'S INTEREST TO THOSE AVAILING THEMSELVES OF THE CONVERSION PRIVILEGE.

This offer is made to holders of the maturing bonds and is not open to other investors. The bonds to be issued under this proposal will be substantially of the same character as those which are maturing, except that the exemption from taxation does not apply to the new issue.

Dated at Ottawa, 8th August, 1922.

Holders of the maturing bonds who wish to avail themselves of this conversion privilege should take their bonds AS EARLY AS POSSIBLE, BUT NOT LATER THAN SEPTEMBER 30th, to a Branch of any Chartered Bank in Canada and receive in exchange an official receipt for the bonds surrendered, containing an undertaking to deliver the corresponding bonds of the new issue.

Holders of maturing fully registered bonds, interest payable by cheque from Ottawa, will receive their December 1 interest cheque as usual. Holders of coupon bonds will detach and retain the last unmatured coupon before surrendering the bond itself for conversion purposes.

The surrendered bonds will be forwarded by banks to the Minister of Finance at Ottawa, where they will be exchanged for bonds of the new issue, in fully registered, or coupon registered or coupon bearer form carrying interest payable 1st May and 1st November of each year of the duration of the loan, the first interest payment accruing and payable 1st May, 1923. Bonds of the new issue will be sent to the banks for delivery immediately after the receipt of the surrendered bonds.

The bonds of the maturing issue which are not converted under this proposal will be paid off in cash on the 1st December, 1922.

W. S. FIELDING.
Minister of Finance.

Your Ideal of Service Is Our Everyday Practice

THE service which you would consider ideal is prompt shipments to satisfy steady consumption and ample stock to take care of larger quantities demanded by emergencies.

This is the service Dominion Oxygen Company Limited offers to you for your oxygen and dissolved acetylene supply—plus:

A contract based on generous terms and friendly relations.
The latest type of cylinders, safe, light in weight and strong.
A liberal policy of cylinder loans.
A desire to meet your requirements.
Oxygen and dissolved acetylene of a higher standard of purity than is usual for commercial use.

We will appreciate an opportunity of placing our proposition before you and quoting prices, whether for small or large quantities, before you make arrangements for the year's supply.

Boosting Production

BLISS

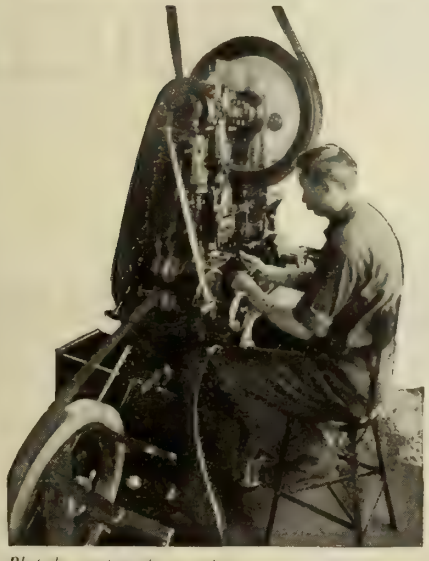

Photo by courtesy of our customer

BOOSTING PRODUCTION is an ideal way to reduce costs. In production from presses this may often be done by the use of feeds. The picture shows a BLISS No. 19 Inclinable Press specially equipped with a roll feed. It blanks, pierces and forms at one operation—production 55,000 to 60,000 in ten hours—material cold rolled strip stock .020 thick.

BLISS Inclinable Power Presses are rigid, convenient and adaptable. Built in a great number of sizes, they may be equipped with simple practical attachments which give them a wide range. There is a BLISS Press to meet every sheet metal working requirement.

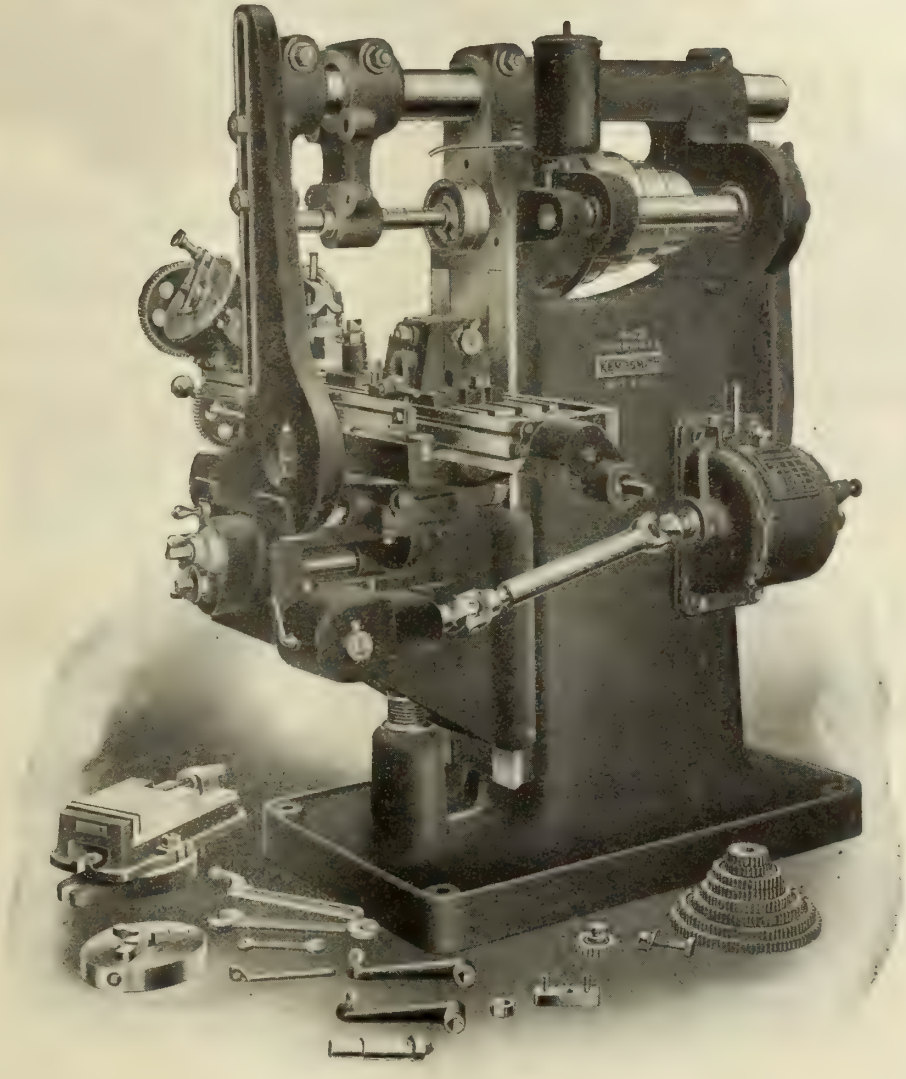
KEMPSMITH



No. 2 UNIVERSAL

Thirty-two years ago the Kempsmith Company began its career in a small one-storey frame building. To-day there are four main buildings, aggregating 106,000 square feet of floor area, besides various storage sheds, etc. Every building of the plant is a model of its kind.

It has always been, and will continue to be, the purpose of the Kempsmith Company to produce machines of the highest quality only, suited to the most advanced practice.

Every machine, whatever size or type, is put to test under cuts and conditions purposely more severe than it will encounter in even the most progressive shops and when it leaves our factory it has our positive and definite guarantee back of it.

Literature will be gladly sent upon request

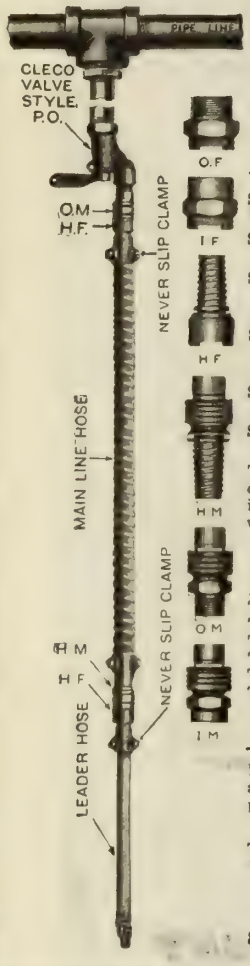
Cleco Pressure-Seated Air Valves

Bowes Air Hose Couplings—Cleco Never Slip Hose Clamps — Cleco Grooved Hose Nipples and Hose Clamp Tool



STYLE O.F. is an Outside Thread Female Pipe End. Made in sizes ⅜-inch to 1½-inch.

STYLE I.F. is an Inside Thread Female Pipe End. Made in sizes ¼-inch to 1½-inch.

STYLE H.F. is a Female Hose End with spiral shank to insert into the hose and has groove for the Never Slip Hose Clamp. Made in sizes ¼ inch to 1½-inch.

STYLE H.M. is a Male Hose End with spiral shank to insert into the hose and has groove for the Never Slip Hose Clamp. Made in sizes ¼ inch to 1½-inch.

STYLE O.M. is an Inside Thread Male Pipe End. Made in sizes ⅜-inch to 1½-inch.

STYLE I.M. is an Inside Thread Male Pipe End. Made in sizes ¼-inch to 1½-inch.

The Male and Female Ends of Bowes Couplings interchange in sizes ¼-inch to ¾-inch. Sizes 1-inch and 1¼-inch interchange. The 1½-inch ends interchange only with themselves.

BOWES COUPLINGS

Are instantly connected or disconnected.
They are absolutely air-tight under all pressures.
They quickly pay for themselves by stopping costly leaks.
They interchange in sizes most commonly used.
They have no loose parts to be mislaid or lost.
They are made of brass and will not rust.
The U-shaped Gasket interchanges in couplings ¼-inch to ¾-inch.

CLECO AIR VALVES.

Style R.A. **Style P.O.** **Style A.**

Style P.O.—Made in sizes ¼ in., ⅜ in., ½ in., ¾ in., 1 in., 1¼ in., 1½ in., 1¾ in., and 2 in. Pipe Outlets. Inlets are one pipe size larger.
Style A—30° Angle Valves, are made in sizes ½ in., and ¾ in.
Style R.A. Right Angle Valve, made in sizes ¼ in., ⅜ in., ½ in., and ¾ in.

CLECO GROOVED HOSE NIPPLES

Grooved Nipples when attached to the Hose with Wire Clamps as illustrated cannot "blow out." Wire clamp tool shown below applies the wires to hose.

The Lighting Hose Clamp Tool illustrated applies wire clamps at a cost of 1½ cents each.

Use Annealed Wire No. 14

In stock: Riveting and Chipping Hammers, Air Drills, Emery Grinders, Sand Rammers, etc.

IMPORTANT:—The Small Leaks in your "AIR LINE" mean serious loss in DOLLARS. Have you any idea of the amount of "Air" wasted in small leaks at your connections? Air Leakage through 1-16 in. opening equals 5.32 cu. ft. per minute at 80 lbs. It will pay you to install Bowes Couplings and Cleco Valves, which will stop costly leaks.

Bulletin No. 50, mailed on request.

THE MODEL HOSE LINE illustrated shows correct styles of couplings and valve to use and proper way to attach the Cleco Never Slip Hose Clamps to Bowes Couplings. No "blow-offs" can occur when "Cleco" Clamps are used.

Jigs and Fixtures Used in Producing Car Axles

Milling Trunnions on Steering Arms—Machining Front Axle—Locating Forging in Jig—Brake Drum of Unusual Design—Grooves for Dispelling Heat—Eccentric Work on Pivot Pins

By ROBERT MAWSON

MANUFACTURING automobile car axles involves interesting operations and the methods adopted in the large plant are here described and illustrated. Fig. 1 shows the jigs and tools used when hollow milling the steering arms. The forging, which has been previously drilled and reamed, is located by this machined hole on the pin A. The arms of the forging are located by means of the clamp B which force the piece back into circular grooves in the vertical wall of the fixture when the nut is tightened onto the clamp. The hollow mill C is then fed down by means of the revolving drilling machine spindle and the two ends of the steering arm machined to 11/16 in. dia., the mill being then moved over to the other position for the second prong.

Another style of steering arm is shown at D, also the style of hollow mill used for the operation; this second steering arm is also milled in this fixture. The arm is threaded 11/16 in.—16 threads per inch in a subsequent operation. It will be noticed that the fixture is provided with a second boss F which has been designed on the tool so that if at any time it is desired to machine a steering arm of the opposite hand the tool will take care of the work by fitting a locating pin in this boss on the casting.

Machining Front Axle End

The front axle end used on the Dusenberg automobile requires some interesting methods during its manufacturing in the shop. The part is made from a forging and the first operation is boring the large center hole and one of these elements after this work has been performed on it is shown in Fig. 2 at A. The piece is then placed into the jig B and located with the center plug C that fits into the bored hole. The clamp D is next dropped down and fastened with the pin as shown. A screw plug shown in the center of this clamp is then tightened down onto the forging and pressing against the spring pad E squares the piece in the jig. The swinging strap F is next dropped and this is held with a cam shaped screw. The following holes are then drilled, one 15/16 inch for the axle pin, one 7/16 inch for the lock pin, two holes for 11/16 inch 20 threads, one 9/16 inch in the spring pad and one ¼ inch. It will be observed that this jig is turned over into different positions for several drilling operations, legs or machined faces being provided in order to bring the guide bushings in line with the drills used.

Both clamps are fitted with guide bushings through which holes are drilled into the forging and in service this tool is giving the best of satisfaction both as regards quality and quantity of production. One of the finished drilled forgings is shown in front of the tool and will give the reader some idea of the work performed on it when it is compared with the piece at A, which is the rough element before drilling.

The next illustration Fig. 3, shows the fixture used for the first milling operation on the front axle end. The forging is again located with a plug that fits into the large center bored hole and the outer end rests on two height pins A. A plug is then placed in the holes B and the height pins which are screwed into the fixture are adjusted until this plug sets in a perfectly horizontal position. The clamp C is then tightened onto the forging, by means of the nut shown, to hold it securely for the milling operation. A gang set-up of cutters are then fed across the bosses shown at the forward end with the fixture located and held to the milling machine table in the usual manner and the sides of the four bosses machined to the correct width as shown.

The same fixture is employed for the second milling operation but set-up as shown in Fig. 4. The forging is again located wth the large plug that fits in the center hole, and the pin A fitting in the 15/16 inch hole machined in the forging with the jig, and this locating also fits in the fixture. Two supporting pins B are next screwed against the under side of the spring pad to hold it rigidly for the machining stresses, and the strap C being fastened down holds the forging securely during the milling operation. When the element is in the position as shown the spring pad surface D is machined using an end mill in a vertical milling machine for the operation.

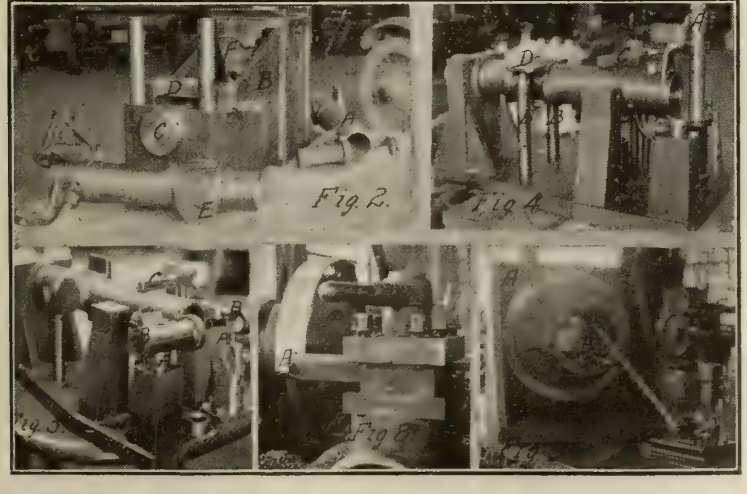

Fig. 2.—Drilling front axle end. Fig. 3.—First milling operation on axle end. Fig 4.—Second milling operation. Fig. 8.—Turning brake shoes. Fig. 9.—Testing axle pinion housing.

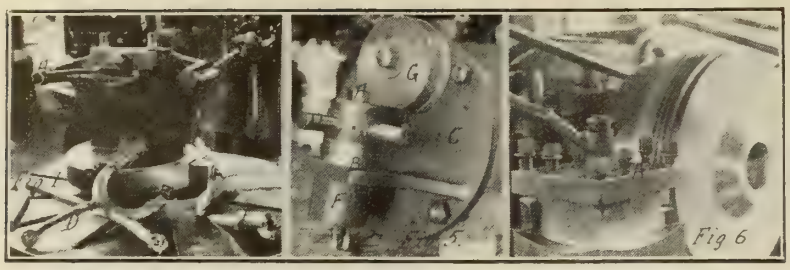

Fig. 1.—Hollow milling steering arm. Fig. 5.—Grinding differential spider arms. Fig. 6.—Turning grooves in brake drum.

The last operation on the differential spider is grinding the arms; these have been previously turned on centers in a lathe, but in order to get them absolutely smooth, to size and at right angles to each other, they are ground with the fixture illustrated in Fig. 5. The forging is located by means of a key on the plug A, a nut and washer holding the element to the face B. The face plate is fastened to the grinding machine with the bolts shown, being located by means of a register fitting a tongue in the grinding machine head. The arm D is then ground to size, the index pin E is then pulled out of the indexing bushing in the casting F and the spider moved around until the plug that located it fits the next position determined with the pin E which will drop into another bushing. The second arm is then in line for grinding and so on until all the four arms have been ground to size. A balance weight G is provided on the fixture so that the fixture will revolve smoothly during the grinding operation.

The brake drum is of rather unusual design being made with grooves in order that the heat generated during the braking action can be dispelled by having more surface in contact with the air, these grooves providing this additional surface. This drum is first bored and turned all over and then held in the chuck shown in Fig. 6. The six grooves which are 5/16 inch wide and ⅜ inch deep are then machined using the multiple tool set up held in the tool post A. The machining of the grooves was tried first to form all six at once, but it was found that better time could be made by turning three and then setting over the tool post and machining the other three in separate setting, a guide being provided in the multiple tool to drop into one of the grooves so that the operator will know when he is in the proper location for the second forming of the grooves.

The steering knuckle pivot pins used with the hydraulic brake cylinders are manufactured in rather an interesting manner. The hole is made eccentric with the shank so that as the shank is rotated by the automobile operator through the brake rods the cylinder will allow the fluid used to bring the braking action into effect and slow down or stop the car as desired. The pin is first machined in a lathe to the shape shown at A in Fig. 7. This is a somewhat ordinary machine shop operation and is done by turning the shank B with one pair of centers and then using a throw dog center at the shank end equal to the amount of eccentricity, in this case 11/32 of an inch, and using a new center at the head end equal to this throw. The turned pin is then placed in the fixture C with the head end protruding as shown, four screws placed in the knurled section D are then tightened down as these are fitted with copper shoes the surface of the pin is not injured.

It will be observed that the fixture face plate is attached to the lathe in an offset position, in other words not on the true center line of the machine, the amount of this offset being equal to the eccentricity desired, namely 11/32 of an inch. The following operations are then performed on the head end of the element bore, and ream 1½ inch diameter 1½ inch deep, counterbore 1 9/16 inch 1/8 inch deep, turn outside diameter to 1¾ inch and for a distance of 1⅝ inches. The tools used for the work are operated in the turret head of the machine and the set-up used when reaming and turning the outside may be seen at F and one of the finished pins is shown at G.

Turning Brake Shoes

Turning the face of brake shoes is considered one of the difficult problems in many automobile manufacturing plants; these elements are made of rather thin section and have a wide face to be machined which must be true, otherwise the brake would not operate smoothly. This problem has been solved in a simple and positive manner at this plant and is shown in Fig. 8. The brake pin holes are first drilled and reamed in the bosses, the casting being located in the jig from the outside rough surface of the piece. Two of these brake shoe elements are then placed on the face plate fixture shown in the illustration, being located and held with pins that fit accurately the reamed brake pin holes. The braking surface is then turned with the tool A, and as the castings are located correctly, held firmly and the tool used as may be seen is also of rigid construction, the surface machined in all that can be desired.

The fixture used for testing the rear axle pinion housing is shown in Fig. 9. This operation is performed after the element has been completely machined. The housing is located in the fixture by means of a turned register which fits into an accurately bored hole in the vertical wall A of the fixture. The three clamps shown are then tightened up slightly not to hold the part securely but merely to prevent it falling out. The dial B of the indicator is then set to zero and the housing revolved in the register hole of the fixture, the tester taking the reading from the indicator dial to see what variation if any is present in the large machined hole in relation to the locating register. On this element a tolerance of two thousands of an inch is permitted and any housing not meeting these requirements is rejected as not being within the accuracy demanded on this part.

This will convey to the reader some idea of the carefulness of the machining operations demanded at this plant and such requirements could only be complied with by the use of accurate jigs and fixtures and yet meet production; without such special tools the problem would resolve itself into a tool room proposition.

1922 VICTORY BONDS

Returns received to date by the Department of Finance indicate a very general acceptance of the proposals for the conversion of 1922 Victory Bonds into new bonds bearing 5½ per cent. interest and running for a further period of five or ten years as desired. Many holders would like to take up considerably more of the new bonds than they have of the maturing issue, but this is not permitted as cash subscriptions are not being invited at this time. It is open, of course, for such persons to add to their holdings of 1922 bonds by purchasing them in the market or from holders who require the cash and then to surrender them for new bonds. It is known that this is being done.

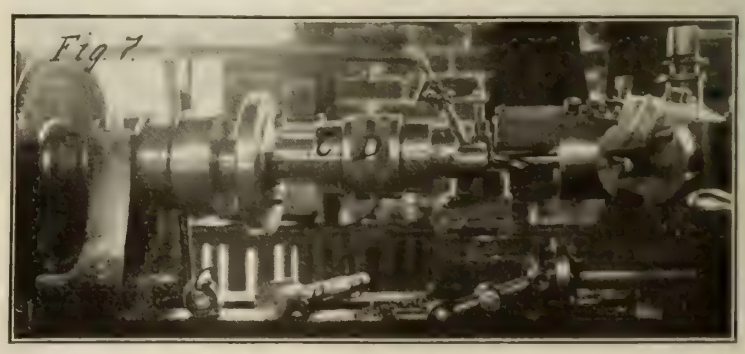

Fig. 7.—Machining steering knuckle pin.

Training of Apprentices Has Its Speed Limits

Theory That There Are Short Cuts to Destiny Too Much in Evidence—Hamilton Manufacturer's View—Responsibility of Home and Parent—Present-Day Ease and Old-Time Fire—Boys Still Indentured by Bertram's

THAT manufacturers of machinery are not depending altogether on the prospect of a supply of apprentices from the technical schools is evident from the encouragement they are holding out to boys whose ambitions urge them toward the engineering field. Not that there is any serious fault found with the idea of technical training in the schools—anything that educates tends to higher standards—but the apprentice will always be an adjunct of industry and there are different methods by which the same end may be achieved. It cannot be imagined that a manufacturer should disapprove of technical education for there are those at the head of Canadian industries who owe much of their success to well-disciplined, early association with technical training and the most practical kind of application in actual machine shop practice.

But there is a feeling to-day that the youth from the technical school cannot always content himself with the position available to him when he emerges from the shell of instruction to make his first scratch upon an industrial pay-roll. There is a great difference in boys; to some the first rung of the ladder and a clear vision ahead is all that is required, while others have given the impression that they have arrived before they are there. They demand positions for which they have not been equipped through experience.

Fifteen the Preferred Age

"Eighty per cent. of the apprentices we have entered in our shop have carried on until they were through," said P. F. Ford-Smith of Hamilton, while discussing the apprenticeship question with Canadian Machinery. In this shop, the boy is introduced to his chosen calling under modern practice and conditions—careful supervision, well-balanced arrangement of tools, and reasonable encouragement.

"We prefer to have a boy at the age of fifteen or sixteen," continued Mr. Ford-Smith. "The boy's parents are first consulted, they are advised fully as to the conditions under which he enters our employ, while on our part, we must convince ourselves that he is adapted to the work, and that he is the kind who should make good. In our experience, however, we find that the boy coming from a well-to-do home, who has everything he desires and has little to worry about is not the most satisfactory. Very often his parents interfere with his application to work, desire that he should have protracted holidays and are anxious that he be preserved untested and unsoiled. The word apprentice doesn't appeal to this class of people.

"In my opinion there is nothing like the fire of experience and wisely directed discipline. The old-timers passed through it and on looking back declare it to have been very good. But we are living in a speedy, pleasure loving age. If there isn't a royal road to destiny, a boy of eighteen is prepared to map out one. He knows, and he must be moving on. Speed, I am afraid, is the hand-maiden of superficiality. At least it is in the machinery business, for I've been over the road myself. Many an old-timer from the Old Country will tell you about having to jump out of bed at five o'clock in the morning, as a boy, take his day's meals with him to the shop and consider his turn at technical schools as part of the day's work without inconvenience to his duties as an apprentice and without reward. Why, training was such that at thirteen a boy knew as much about hydrostatics, mathematics and all the rest of it, as some of to-day's youths graduating from the universities. Remember, I am not advocating these strenuous courses for to-day. But I want to point out that it was a system that produced mighty thorough engineers.

Encouraging the Boy

"When a boy enters our employ as an apprentice, we pay him 14 cents an hour. I will admit that he has a little more to do than the boy who has the job of delivering the early morning or the evening paper, and is paid $5 per week for heaving the news of a palpitating world in the general direction of the patient subscriber. In time the boy may learn to strike the house, but one can't very well call that a life mission. The boy in the shop is supposed to be working toward a destination. He begins work on a lathe and in time becomes acquainted with gears and mechanisms and blue prints. His training includes a period in the designing room. Our system is to keep quite as close a record of that boy's conduct and development as does the school. We have merits and demerits and at the end of a certain period, say six months, we present the boy with a micrometer, or a square or some other necessary part of a kit, by way of reward for good work. Some boys, of course, are quicker than others, but we have tried to impress the importance of thoroughness and of serious application. These are the things that count in the end. I recall one boy we had with us who was somewhat exceptional. Smart as a steel trap, he seemed to outstrip everything, and the development of importance in his vicinity was something to give one pause. He was a good speaker and had ideas about organizing his fellows for various purposes. He is now a minister or evangelist somewhere in the States where he has scope for a rich imagination without restricting it to the hundredth part of an inch.

"As manufacturers, there appear to be

Developing pattern makers at the woodworking department of a large technical school.

quite a number of us who think the adolescent act is a little too hard on the parents who cannot afford to keep grown children at school for the period required. That extra two-year period might have come easier had it been made a matter of five and ten years. Manufacturers nowadays want to do the right thing by young people. They are the ones who must carry on, but it is first essential that the home be right. That is where the tendencies that we sometimes deplore in present day rush must be safeguarded against. We parents must have confidence in each other. Given the right outlook, there can be no doubt about the result.

"Apprentices of to-day are reaping the advantage of yesterday's application. In the early days the period of training was seven years. Now it is four years, but the development of machinery has been such and the progress made in the application of electricity, pneumatics, automatics, that one might almost say that the intelligence of a machine goes a long way in the elimination of that extra three years. Operations that were once considered quite a delicate matter have been reduced to absolute simplicity. Still there is wonderful scope for brains in the engineering field.

Technical System Not Perfect

"Let me repeat that I have no complaint to make with regard to technical education. It increases a boy's fund of knowledge and improves his usefulness. We cannot all agree that the system is perfect, as for example, requiring a boy to break away from his work in the shop during the middle of the afternoon in order to attend class, but there is nothing that cannot be remedied in time. You may count on me as a friend of the boy and of anything that makes him a better citizen. If a crisis comes, we will undoubtedly have our apprentice requirements met. It developed that way during the war, although not all of those who went out as machinists and toolmakers afterwards could properly be called such. Some remarkably good men may be numbered among those who began their apprenticeship after the age of twenty. Such men have an idea of responsibility not always found among the youngsters and turn out to be most dependable. One sometimes wonders where our supply of apprentices for all industries will come from, but I guess the law of supply and demand will take care of that question, as it does of most others."

Gentlemen Apprentices

Mr. Ford-Smith recalled earlier days when scions of prominent families identified themselves with industry as gentlemen apprentices. Some of these boys made good, but the majority did not and were terribly bored. Such apprentices however, netted a firm £200 each and it is known that receipts from this source sometimes paid the salaries of the executives in the business. The amount had to be high, however, because breakage and spoilage were sometimes considerable items.

Apprentices Bound Here

John Bertram & Sons Co. still employ the indenture system. This is a matter between the firm and the parent or guardian. A fee of $100 is required, and if this is not paid at the time the boy is bound as an apprentice, the sum of $2 is retained from his weekly salary. This amount is placed in a bank in the boy's name and at the conclusion of four years, when his training is complete, he is handed back his $100 with accrued interest. It is quite a nice little nest egg.

"We prefer that a boy should have two years in the collegiate before we take him on," said Chas. E. Dickson, secretary-treasurer, "and we consider that the best age is about fifteen years. A great deal depends on the boy, of course. Among the best apprentices we ever turned out were three young men about twenty-one years of age. They completed their training and are now doing well. It is not a difficult matter securing machine shop apprentices in Dundas where a trade is pretty much a matter of heredity as in the Old Country. There is a real apprenticeship problem in connection with the foundry industry, but more castings are being made to-day than ever before. Machinery is helping in the solution in such a way that any intelligent man can very shortly become a producer. Improvement in conditions associated with the industry will probably attract more men to it."

MONTH'S EMPLOYMENT RECORD IMPROVES

THE volume of employment in the iron and steel group increased considerably during July, states the Employment Service bulletin, mainly on account of the resumption of operations in several of the railway car shops, which had been temporarily closed down at the end of June. In addition, noteworthy improvement was recorded in the crude, rolled and forged division, supplemented by increases in employment on a smaller scale in boiler, engine and hardware factories and in the production of structural iron and steel. On the other hand, steel shipyards were decidedly less fully employed. All provinces except British Columbia shared in the upward movement, but the expansion in Ontario was more pronounced than elsewhere. The 730 concerns making returns reported 110,130 persons on their payrolls as compared with 102 105 on June 30. There was, therefore, an increase of 8 025 persons or almost 8 per cent. Increased activity on a much smaller scale had been indicated in this group during July of last year but the index numbers for the two periods were approximately the same.

Employment in electrical apparatus has fluctuated considerably since the beginning of the year, but the general trend has been favorable. The largest increase of the year was reported during the period under review, when 239 persons were added to the staffs of the 83 concerns making returns, whose payrolls covered 6,126 persons, an increase of approximately 4 per cent. over their June staffs. Establishments in Ontario absorbed the majority of these workers.

Continued activity in summer operations was indicated in railway construction and maintenance. Statements tabulated from 31 concerns and divisional superintendents indicated a total payroll of 49,259 persons as compared with 45,626 on June 30. The bulk of this 8 per cent. gain was reported in Ontario and the Prairie Provinces, although expansion was also registered in the other districts. The advances made during the same month of last year had been only slightly smaller than for July, although the index number at that time stood considerably lower than for the period being reviewed.

The volume of employment afforded by building construction showed a further increase during July, mainly in Quebec and Ontario. The 328 firms reporting, whose pay-rolls included 19,278 employees, indicated that they had enlarged their working forces by 1,026 or 5.6 per cent since the end of June. Expansion on a much smaller scale had been evidenced in July of last year and employment in the group was on a higher level for the period under review than at that time.

Another large increase in activity occurred in railways during July, 1,794 persons having been added to the staffs of the 125 concerns and divisional superintendents reporting. As the total payroll included 74 361 persons, this indicated a gain of 2.5 per cent. All provinces shared in the upward movement to some extent, but the gains in Ontario and the Prairie Provinces together formed 85 per cent. of the entire increase. The seasonal expansion reported during July of last year also had been somewhat more extensive but the index number at that time was slightly lower than for the month under review.

Shipping and stevedoring.—Varying conditions were recorded in shipping and stevedoring, resulting in a net increase of 396 persons or nearly 3 per cent. Sixty-three concerns reported an aggregate working force of 14 361 employees as compared with 13.965 on June 30. Quebec harbors were very much busier, while at the New Brunswick and Pacific ports reduced activity was registered. The level of employment in this group was very much higher than during July of last year.

It is always advisable to use light pressure when starting to grind on a cold wheel, gradually increasing the force as the wheel gets warm. This prevents the wheel from expanding rapidly and eliminates breakage. This applies particularly to starting work in the morning in cold weather where temperature of room is low during the night, or when wheels are stored in a cold place.

Making Steel Forgings With Header Machine

Intricate Parts Formerly Made on a Power Hammer Now Pressed Into Shape on an Upsetting Machine—Pole Piece is Forged in One Operation and a Ring Gear in Three

By H. E. DILLER

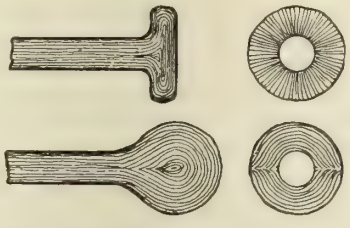
RIGHT forgings usually are made by hammering the metal stock into the desired shape, either on a board, or true drop hammer, or on a steam hammer. Large hydraulic presses have been employed for a number of years in forging shafting and similar shapes which are simple in design. The header machine, which also operates on the pressing or squeezing principle, has been used for forming simple shapes on the ends of rods but only recently has this principle of pressure in distinction to blows from a hammer been used in making forgings of more intricate design. For this reason the operations in the forging plant of the Dayton Engineering Laboratories Co., Dayton, O., a subsidiary of the General Motors Corp. manufacturing starting sets, is of great interest. Here under the direction of Edward Hughes, supervisor, tool division, some intricate forgings are being made on a header or upsetting machine, and experimental development work is being carried on continually to broaden the scope of the machine for this class of work.

The principal advantage of making forgings on the header machine is the direction it gives to the grain of the metal in forging, states the author in Iron Trade Review. The die presses out the metal parallel with the radii of the bar stack, while in a drop hammer forging, the metal is hammered down in the direction of rolling. This causes the grain of the metal to run irregularly in the forging instead of radiating from the center as in the forgings from the header machine. This is more clearly illustrated in Fig. 1 which is a line drawing showing at the top what takes place when a forging is made on a header machine, and at the bottom the direction of the grain of the metal when the forging is made on a drop hammer.

Lower Upkeep Costs

Other advantages claimed for the header machine are higher production and lower upkeep cost. Against these advantages must be weighed the higher first cost of the header machine. Installed, such a machine costs about four times as much as a steam hammer or about eight times as much as a true drop hammer driven on a line shaft. However, the die costs by the different methods are approximately the same, although dies are more apt to be broken when used in the hammer on account of the shocks received at each blow.

The dies are all built in sections and sectional parts are standardized as much as possible to make them interchangeable and to facilitate replacements and repairs. Then when a piece is broken or worn out it can be replaced without the expense of making a complete new die. Time as well as expense is saved by this precaution. The dies and inserted pieces usually are made of a high carbon, chrome-nickel steel heat treated to give toughness rather than hardness. After heat treatment the die is tested and must show a scleroscope hardness of between 65 and 70 to be accepted by the inspection department. The standard metal for dies and inserted parts contains between 0.80 and 0.90 per cent. carbon; approximately 3.0 per cent. chromium, and between 1.75 and 2.00 per cent. nickel. Sulphur and phosphorus are kept low, usually under 0.02 per cent. while silicon averages around 0.2 per cent. and manganese between 0.35 and 0.40 per cent. Occasionally a steel with 3.50 to 4.00 per cent. chromium is used, and a tungsten containing approximately 12.00 per cent. tungsten, 3.25 per cent. chromium and 0.65 to 0.70 per cent. carbon is being experimented with. Die blocks are made from a lower carbon chrome-nickel steel with approximately 0.60 per cent. carbon, 1.00 to 1.50 per cent. nickel and 3.00 per cent. chromium.



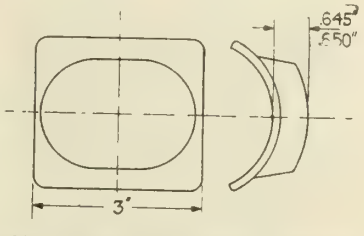


Fig. 1.—(Above) Distortion of grain by a header machine; (below) distortion by a hammer. Fig. 3.—Right, pole piece made in a header machine.

Dies frequently too heavy to be handled by hand are brought to the header machine on an overhead I-beam trolley to which is attached a chain fall. The dies are equipped with eyes screwed in holes in the top and the chain is hooked to these.

To secure the enormous force necessary to press the steel into shape, the 20 h.p. motor is connected to the operating mechanism by means of reducing gears and pinions. In operation the machine operator places a bar of stock against a stop guide and then with his foot presses the control lever. This meshes the driving gears, raising the stop guide, bringing the gripping dies together and pressing forward the shaping die. Space is sufficient for placing the dies three high so that three operations can be made on the same piece of stock to form the forging.

Furnace Burns Gas or Oil

Although at present burning producer gas the furnace can be operated with oil. As originally installed the furnace was heated by eight burners at the back and two at each end. However, it was found advantageous to dispense with the burners in the back of the furnace and to lower the burners at the ends. Now the

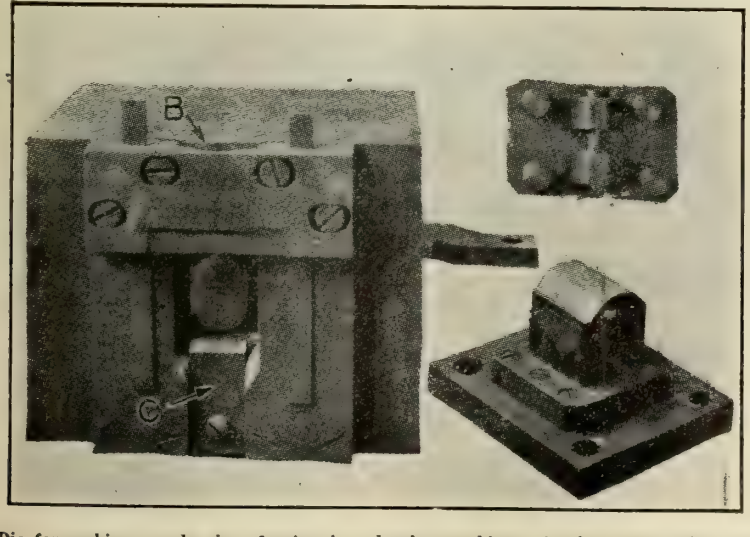

Fig. 2.—Die for making a pole piece forging in a header machine. At the lower right is the plunger die and at upper right is the lug to which the taper wedge controlling the ejector is attached.

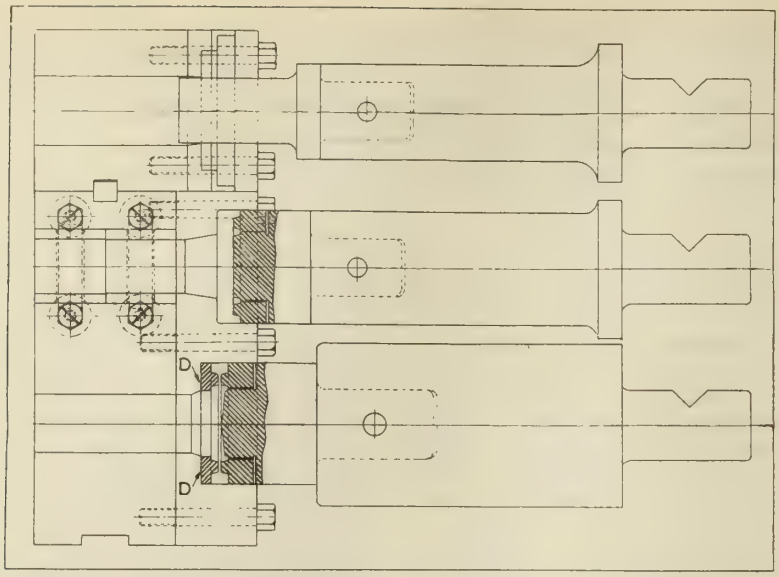

Fig. 4.—Ring gears are made in three operations. The first forms one side of the forging; the next completes it, and the third pushes it from the bar of stock.

end burners are the only ones used and the flame enters at both ends of the furnace about one foot below the level of the bar stock. It then passes up through openings in the roof and, in escaping, heats the two 4-inch gas pipes and the 12-inch air pipe on top of the furnace.

Method of Operation

Ordinarily the stock for the forging is fed into the machine from the front but to make this forging it was necessary to feed the metal from the top. Fig. 2 shows the die, and the hole through which the stock is introduced is indicated at B. Accurately rolled bars, 1½ inches in diameter, are used. The hot bar is set in the die until it rests on the stop C. Then by tripping the machine the movable die shown at the left, Fig. 2, is moved forward by the plunger to which it is bolted. This cuts off the metal exactly the same length at every stroke forcing it into the forming die and making the pole piece, therefore the necessity of having the stock of regular dimensions. Of course, if a lot of bars which do not measure exactly 1½ inches in diameter is received, the bars can be used if they are of a uniform size. This is accomplished by adjusting the stop, C, Fig. 2, so that the length of the piece sheared off will be correct. Adjustment is made by the set screw shown near the base of the stop.

After the pole piece is formed the punch moves out and an ejector arm forces the pole piece from the die, allowing it to drop on the floor.

Helper Controls Machine

At present some difficulty is encountered in the operation of making this forging as the machine operator standing on the machine to feed in the stock is unable to trip the machine as he does when standing in his regular place before the machine. After the helper hands the operator a heated bar he waits for a signal from the operator and then trips the machine. However, arrangements will be made so the operator can trip the machine from his position on top. This incident is interesting as showing the developmental stage of the process and the resourcefulness of the engineers.

Scale is blown from the die with a jet of compressed air after each operation. The die is also swabbed with a light mineral oil to assist in keeping it cool, as no water is used for this purpose.

A somewhat more intricate forging made with three strokes instead of one is the ring gear, Fig. 5, used on the starting clutch and forming the connection between the starting motor and the gasoline motor on an automobile. The 2 3-8 inch round bar stock for this forging is fed into the machine in the regular way. Fig. 4 shows in detail the three dies and the stock. The die in the center performs the first operation. When the stock is put in the machine until it touches the die at the back, the machine is tripped. The side grippers, shown at the left, come in and grip the stock firmly; the ram, attached to the die block at the extreme right, moves forward heading up the bar and putting a shoulder on it. The dies then move apart allowing the stock to be withdrawn.

After the first stroke a ring, which had been placed on the bar by the helper before the first operation, is slid up against the back face of the forging blank. The blank and the ring are then placed in the die in the lower, or second position. The ring may be noted at D D, Fig. 4. As the heading tool comes up it enlarges the outside diameter and thins the blank to the required dimensions, the ring forming a circular channel on the back of the forging and the punch bringing to dimensions the channel formed in the front of the blank by the first operation. The stock with the blank is then taken from the die and placed in the upper die. This pushes the bar out of the blank leaving the finished forging. Then as the die opens the ring falls on the floor and after being reheated the head of stock is ready for another ring. No waste of stock is necessary in making these rings as when the bar becomes too short to handle it is electrically welded to a new bar. Small gear rings without the H section are made in two strokes, it being unnecessary to use the ring which is essential in the second operation when forming the rings with an H section.

The magnet core made in a solid piece 2⅛ x 3 x 3 inches with a ¾-inch radius at the edges offers a somewhat different problem from the forgings described. This is made in two operations from 1¾-inch round stock. The first stroke gathers the stock into a section 2⅛ inch in diameter and necks it on two sides. The second stroke, as the die closes, shears off the gathered piece at point at which it is necked and carries this piece over to the impression in the die. Then as the heading tool comes up it forms the piece to its final shape. The heading tool comes up as the die closes and as the ram recedes the die opens and the formed piece drops out. A special advantage of forging this piece on the header machine is that it can be secured close enough from the header to eliminate the milling operation for length. When made on a drop hammer it always was milled, then finished by grinding. These forgings made on the header are only ground.

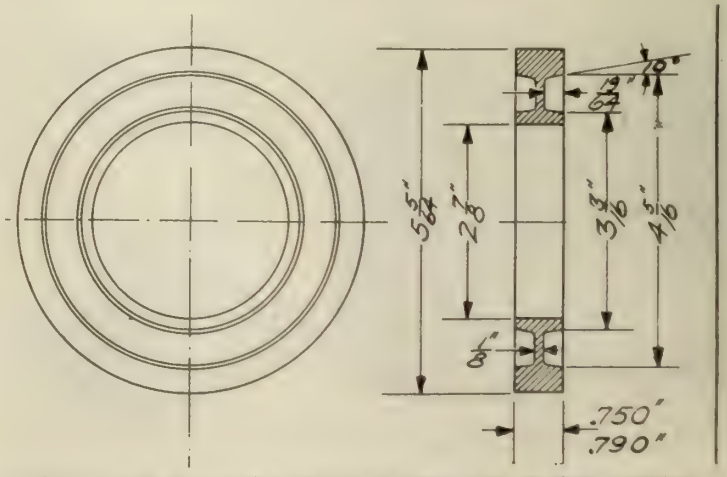

Fig. 5.—Ring gear forging with an H section made in three operations.

Speeding Up Industrial Painting Operations

Easy Manipulation of the Spraying Apparatus—Evenly Coated Surface—Greater Output With Less Labor—Proper Ventilation of Painting Chamber Necessary—Heating the Mixture

FROM the very commencement decorative art manufacturers and artists have used hair brushes and hand methods in finishing coated surfaces. The higher costs and keen competition of modern civilization, however, paved the way for improved methods of applying materials to surfaces to be coated with liquid paints or varnishes o any description.

Where a number of colors or variety of finishes are required on a large surface, or a reasonably large quantity of articles, the spray method of application is to be preferred over the hand brushing process. Not only does it effect a great saving in labor but the speed and uniformity of the work places this process in the front ranks of the attack on the problems of economic industrial management.

The paint gun, or air brush, as it is frequently termed, eliminates the tedious method of slowly and incessantly wielding a hand brush where the hands become covered with paint and the surface being coated is occasionally marred with a stray bristle extracted from the brush. The utilization of compressed air has increased the efficiency of the painter in many ways and the application of liquid coatings at the present time is practically unlimited. From the painting of ship hulls to the finest finishing of commercial articles the spray method has a wide and varied field. Not only in the coating of a surface does the spray gun prove its superiority, but in the hands of a skilled operator, or the workman endowed with ordinary intelligence, the blending of colors becomes a comparatively simple accomplishment.

With a spray gun there is practically no waste of material. The coating may be applied in any reasonable degree of thickness, as the equivalent of two brushed coats may be obtained at one application, if desired. It makes it possible to effectively coat surfaces that would be virtually inaccessible or difficult to cover with a brush, and rough and irregular places are easily and uniformly coated with the spray. One important feature of the spray process is the fact that there is no appreciable wear on spraying apparatus and rough surfaces are coated as readily as smooth. Brush work on brick, concrete and like substances is very destructive to the bristles, and replacements are costly.

One of the difficult problems to contend with in connection with spray painting, however, is the satisfactory solution of proper ventilation and removal of the dangerous fumes. Experiments have been made with small fans and heavy blowers or motor-driven ventilating outfits. Few of these have entirely satisfied the needs for continuous performance.

When paint spraying of small objects is carried on to any great extent it is advisable to install or erect a suitable cabinet or compartment scientifically designed to draw off all the fumes generated by the spraying apparatus. The exhaust fan must be so constructed that the air and fumes which are being exhausted from the painting cabinet do not pass through or come in contact with the motor mechanism. This is a very important factor as the paint or varnish spray is detrimental to the proper working of the motor.

Another condition that should be observed in regard to efficient spraying of paints is that of keeping the material at the proper temperature for maximum effective flow from the container through the connecting hose to the spray nozzles. Moisture, no matter of what nature, is dangerous to high grade work and will often ruin the finished surface. Heating the spray has numerous advantages over spraying with raw, cold or damp air, and liquids below the proper degree of temperature. Special electric heaters are provided for this purpose which are so constructed that the compressed air is thoroughly heated by passing through a red hot copper coil, whereby the air is purified, dried and heated, to facilitate the proper spreading of all paint, varnish, enamel, shellac, and other liquid materials.

Owing to the character of the work the handling of painted articles requires special facilities in transferring them from the painting cabinet to the drying rooms. When the parts are handled in small quantities the drying may be carried on in the same room, but where large production is required it is advisable that drying take place in a separate department. After the coating has been applied the article should be delivered to the drying room with the least amount of handling. The use of conveyors is an ideal method of delivery where the parts can be easily handled by hand, and where the nature of the work will permit the conveyor could be made to pass directly through the painting chamber, the work entering from one side and delivered from the other. Under such conditions the painting operator could control the movement of the conveyor, stopping it long enough to paint the work and allowing it to advance for the next article.

The installation of a revolving table in the painting chamber is also an advantage as it permits the operator to reach all surfaces without touching the article. If a conveyor is used in conjunction with the cabinet it is well to have it on the level of the table so that finished articles can be transferred with the least effort and handling.

PAINTED MACHINE TOOLS

As an indication of the dollar and cents sales value of a suitable finish properly applied to machine tools the following statement was made recently by a Canadian manufacturer:—"At an exhibition in which were shown English, American and German tools a great difference was noted on the finishing. The German and American tools were very much alike and although the machine work on them was vastly inferior to that of the English machines, the application of a dull finish brought out in strong relief every favorable point of their machines so that they seemed to be much better than they actually were. On the other hand the English machines were finished in brilliant enamel glossy finishes which brought out every imperfection in them without giving any distinction to the good points, so that even though the latter were visible to the eye the effect of them was lost on the observer owing to the prominence given the imperfections by the high finish. That did nothing to emphasize the costly brass work and careful attention to detail. The consequence was that the inferior machines (mechanically) had an advantage over those of higher grade.

"I have seen so many instances of a similar nature that I haven't the slightest hesitation in saying that there is a big field in Canada as in England for the development of this side of machinery marketing and a great deal needs to be done to educate our manufacturers to the value of the intelligent use of paint for show room and other sales purposes. It is not enough just to use paint. It must be the right kind of paint in the right place and that is something that should be entrusted in a large way at least only to a man who has made a study of the problem and of the effects of different combinations of colors on the objects to which they are applied."

Safety hoods when installed on grinding wheels should always conform as near as possible to the periphery of the wheel, and should be so designed as to leave exposed the least portion of the wheel compatible with the work. It is advisable that the hoods be adjustable so that the opening in the hood can be reduced as the wheel wears, so as to afford the maximum protection at all times.

Industry Reveals Many Interesting Sidelights

Long Service Records Held by Men of John Bertram & Sons—Machine Tool Maker in Fruit Business—Companies Merge for Cheaper Operation—U.S. Buys Canadian Machines

WHERE grandfathers and fathers and sons and sons-in-law are actively engaged in the same industry, one natually expects to hear of Old Country industrial heredity, or of family specialization for generations in various departments of one particular calling. But although the setting might well be England, and eloquent of scenes that are peculiarly of the Old Land, it is not actually so. It is Dundas, Ont., and the plant that of John Bertram & Sons Co., Ltd. Here are men who have been "on the strength" for 25, 30, 40, 50 years. In fact, there are men who, like George Turnbull, were on the payroll when the present Gen. Sir Alex. Bertram was also at work there at a dollar a day, and there is still that mutual friendliness which quite as whole-heartedly and acceptably greets him with "Hello, Alex.," when he visits the plant, as in those youthful days of 60 years ago. Loking about him he still sees sons and sires and grandsires and great-grandsires who have grown up in the industry. It is one place where a man's record is no flitting thing of a year or two and where loyalty and co-operation have surely counted as appreciable factors.

It was somewhat amusing recently facturer a great length of time to distensive plant, a visitor was introduced to one of the young men at work on a machine. It was here that the conductor, with a twinkle in his eye observed, "Of course, Bill is hardly one of us yet; he has only been here eighteen years."

* * * *

It has not taken a machinery manufacturer a great length of time to discover that there is a far greater spread as between the point of production and that of consumption in the fruit business than there ever existed between the production and sale of a miller, a lathe or any other machine tool. Having recently disposed of a farm in the Niagara district he retained the privilege of harvesting and marketing this year's crop. Peaches were very plentiful and on going over his record he cites a price of nineteen cents from the marketers for eleven quart baskets of fruit at a time when the price of the same in Toronto was around seventy-five cents. From the nineteen cents had to be taken the cost of baskets and picking, to say nothing of other items, leaving very little for the boy. "If machines sold on that basis," he observed, "we might be able to afford an occasional period of depression."

* * * *

Discussing salesmanship in machine tools recently, a manufacturer was asked which, in his opinion, had given the more satisfactory results, the man with a practical, working knowledge of machine tools, or one with no training whatever. He replied that a happy combination of the two naturally appealed to him, but that it was difficult to obtain such a one. "The man with practical training is too much given to discussion or argument with the prospect on matters that draw him no nearer to the sale and very often antagonize," he replied. "On the other hand, the untrained man loses out because he is not as familiar with his line as he might be. In either case, however, where there is tact, a knowledge of human nature, honesty and familiarity with the line, sales will result. Personally I ilke to do business with a practical man, but I also know of cases where the unskilled salesman gets it across. But he is a better man if he has had practical knowledge, and has developed that happy faculty of knowing what to say at the right time, and ability as a good listener. Honesty is an essential, for in the last analysis, a machine tool speaks for itself and therein is the salesman judged."

* * * *

Marked progress has recently been made in the development of machinery used in cutting, polishing, grinding and otherwise working heavy stone used for building or monumental purposes. The Pollard Manufacturing Company at Niagara Falls, Ont., have specialized in this, and while the Canadian market has its limitations, considerable business is being done with American buyers. There is here a drawback of duty on raw material which makes competition quite feasible. It is interesting, that from a grinder designed for certain operations in shell-making during the war, there has been developed a machine employed in the production of stone balusters or columns such as used in large public structures. Activity in the building industry has caused improved demand for this class of machinery and much manual work has been eliminated or simplified.

* * * *

Once again, a merger has been announced having for one object, at least, the development of economy in operation. This time the Ramapo Iron Works with a plant at Niagara Falls, Ont., and N. Y., is merged with the Ajax Forge Company with plants at Chicago and Superior, Wis. The merged companies will form a subsidiary of the American Brakeshoe and Foundry which has a plant in St. Thomas, Ont. Thos. E. Akers, vice-president of the Niagara Falls Ramapo plant, will be vice-president and general manager of the Ramapo-Ajax coropration. He is reported as stating that many economies are anticipated by merging under one manag ment. Both companies have specialized in safety devices for railroad operation such as frogs, crossings, switches, switch boards, guard rails, clamps and industrial cars and car equipment. Proposed plans call for sale of $2,250,000 first mortgage 20 year bonds which have already been underwritten.

Canadian Machinery learns that the Canadian plant of the Ramapo Iron Works has been fairly well employed up to the present time on railway work, but not to capacity. No extensions are in immediate prospect, athough the evidence of any considerable amount of railroad or other activity requiring such equipment might lead to a development of that kind. At the present time a foundry at Niagara Falls is kept busy on work for this concern.

* * * *

It is predicted that motor truck production this year will reach $250,000,000 and that sales of tires, gasoline and equipment and accessories will bring the amount up to one billion dollars. These figures are indicative of the extent to which motor trucks are being employed, not only for commercial and agricultural purposes but also for passenger service. In United States serious consideration is being given to a proposal to link all large cities by trunk lines of motor buses. With improvement of roads in Canada, the use of trucks in interurban service of all kinds is bound to increase. There are in fact rumors that a gigantic truck corporation is proposed to compete with the network of trolley lines which Sir Adam Beck has in view as a development of hydro-electric service. Statistics available from districts where trucking has been most extensively employed, indicate the extent of competition offered to steam and electric lines. Less than three per cent. of the milk that is brought into Cincinnati is transported by railroads even under normal conditions and milk and produce dealers in the vicinity of Cleveland are reported to be using trucks altogether. Milk coming into Philadelphia by trucks now amounts to 64,169 quarts daily, and it is estimated that trucks operating out of Louisville, Kentucky, will soon be handling 500 tons of supplies both on the outbound and inbound trips. Under normal conditions the trucks and interurbans handle 75% of all perishable foodstuffs in Kentucky and Southern Indiana. The meat packing industry has also adopted motor transportation. Fifteen motor express lines for handling livestock shipments within a radius of 45 miles of Kansas City have been established.

Practical Ideas From Practical Men

COLORING STEEL BLUE

By C. Howard

Polished steel articles may be given a blue finish by placing them in heated charcoal. The pieces of steel to be colored must be smooth and clean. The charcoal is powdered and placed in a box made of steel or iron plate. The steel being blued must be taken out from time to time and dusted with finely powdered whiting. The piece should be watched and when the desired shade of blue is reached it is removed and allowed to cool, then cleaned and oiled.

It is often desired to color a piece of steel and still avoid using heat to keep it from warping. This can be accomplished by first cleaning the piece thoroughly and then covering it with a solution containing ten parts of water to one part of nitric acid. After it has turned a bluish shade wash it thoroughly with warm water, using a soft cloth; then wipe it dry. Finally rub it well with linseed oil.

TOOL LAYOUT FOR PRESSED STEEL TRUCK WHEEL HUB

By Geo. Barrett

Many designs of automobile wheel hubs are now made for the various types of cars and in order to attain and maintain rapid and economic production it is necessary to provide adequate yet simplified tooling to assure duplication and interchangeability in the parts manufactured.

The accompanying sketches herewith illustrate the method used in producing a motor truck hub on a Libby turret lathe. The part is made of electric steel casting, finished in two chuck sittings at an average rate of 35 minutes each. Fig. 1 represents the sectional view of the hub with the various finish marks and dimensions; the latter indicate the close limits to which surfaces have to be machined.

Fig. 2 shows the general arrangement of tools for the first setting, the tools A, C, D and E being located in every other hole on an octagon turret. The hub is gripped on the outer end, using a self-centering chuck. The bore is first roughed out with boring bar A and roughing tool B on cross slide. The turret is indexed to next position and boring tool C increases the hole to reaming size, the reamer D removing the final .010 in. of metal. This completes the boring of inner ball cup seat, the length being taken care of by the special facing tool E, which is set to the required distance and has a revolving washer at the end to prevent scoring of ball cup seat. The forming tool F on cross slide is used to bring the diameter and width of wheel centre to within about .030 in. of the finish dimension, after which the facing tool G completes the operation.

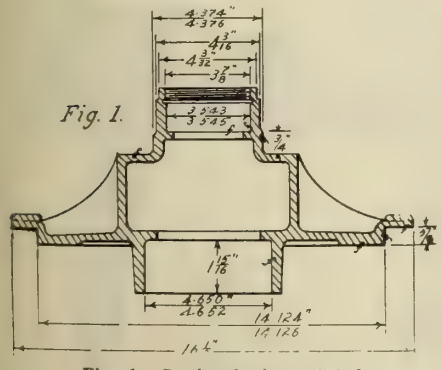

Fig. 1.—Sectional view of hub.

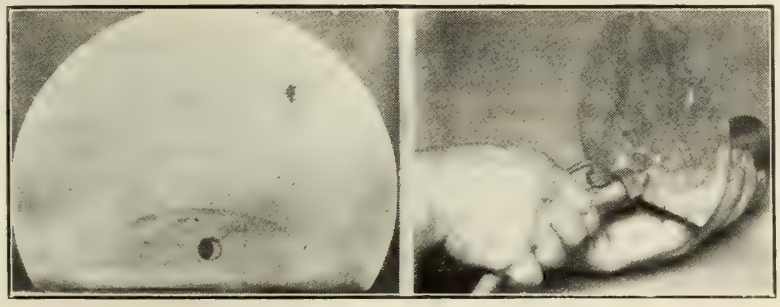
The hub is then reversed and held in chuck as shown in Fig. 3. The outside is finished by roughing tool A and forming tool B on cross slide, the threading being performed by the self-opening die on turret C. It will be noted that the shank of this die is made to slide into the holder set in turret head, and is prevented from turning by the feather key D. This construction has given good satisfaction in producing both inside and outside threads, as when the chasers are once started to cut, the irregularity of the feed is taken care of by the coil spring inside of die holder.

The boring is similar to inner side, only using an eccentric tool E for forming diameter for thread and undercutting for clearance. The boring bars and reamers are all of the adjustable type, and are ground between centres, to centralize cutters and pilot with the steel bushing inserted in lathe spindle, thus relieving the operator from grinding and setting the tools.

AIR HOSE SHIELD

By H. Moore

Air hoses are used frequently for cleaning purposes; cleaning out holes, slots, etc., or blowing away cuttings from machines, and for this reason the handy device here illustrated was devised. A large percentage of eye accidents may be traced to chips and dust rebounding under the strong pressure of air, yet it is seldom that one sees a guard of any kind attached to an air nozzle. This may be from the fact that it is difficult to hold anything securely on the tapering surface of the average nozzle. Improvised shields are often made out of a piece of stiff cardboard, but it is advisable to have the guard made of metal stock. The one here shown is made of thin sheet steel of circular shape bent over as indicated. Two holes are drilled, their location in each section being slightly out of alignment; this is done for two reasons, first to give an inclined surface to deflect the chips and also to increase the grip on the noz



Showing application of air hose shield.

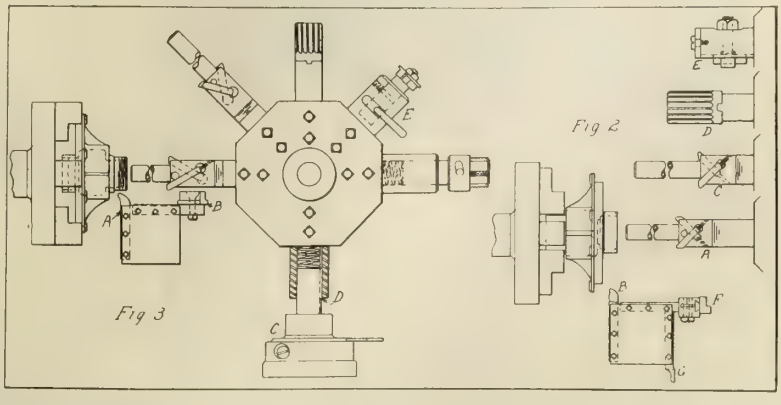


Fig. 2.—General arrangement of turret tools for first setting. Fig. 3.—Tool set-up for second operation.

New Things in Shop Equipment

SPECIAL MILLING MACHINE

As a general rule when a new type of machine is designed the chief point aimed for is high productive qualities, but the small milling machine illustrated was made for accuracy rather than production. It is specially designed for cutting racks and pinions used on computing scales and as extreme accuracy is essential on work of this nature, each portion of the new machine received the closest attention.

Several attempts have been made previously by other concerns to adapt the regular type of miller to this class of work, but this move has been found impracticable, because, while close limits are obtained, they are not accurate enough for computing scale work. Therefore, in starting the machine shown, the Ford-Smith Machine Co., Hamilton, Ont., who designed and made this special miller, decided to step out of the beaten path and make something entirely different.

Up to the present time, others who have tried to mill these racks depended upon the screw in the knee to secure the proper location of table for each tooth cut, but even when the screw was exceptionally well made inaccuracies soon developed, making it useless as a proper locating medium. In the new design no attempt to use the screw as the locater has been made, but a series of teeth, properly spaced, and made of high grade tool steel, has been designed and placed at A. These teeth are each separate blocks of tool steel and are carefully ground until the pitch required is absolutely correct. This entails considerable work and skill, but once completed the teeth placed alongside of each other form a permanent templet from which the table can be located to cut the rack accurately. To further ensure accuracy the pointer B is used. Here is how the table is located before each tooth is cut.

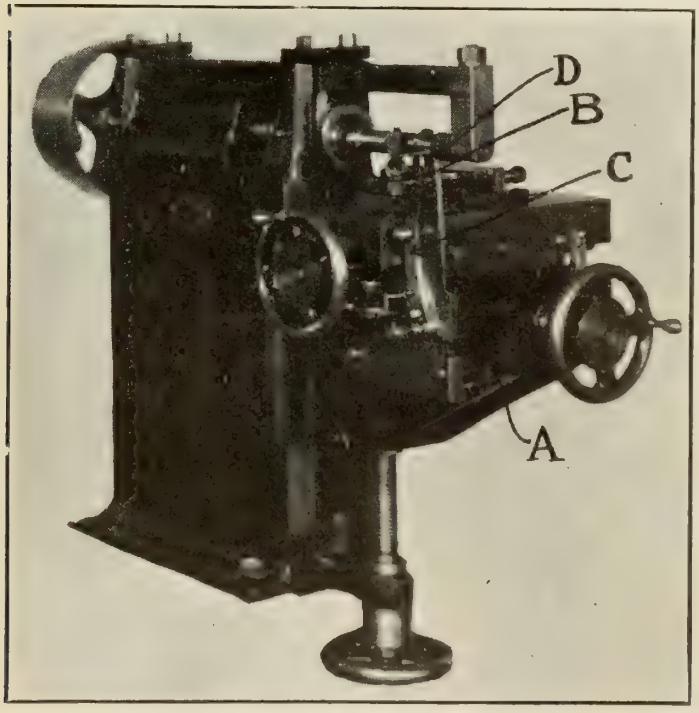
The operator places a similar pointed tooth on the end of the lever C into the first tooth of the series A. He next operates the handle of table until the pointer B corresponds with a mark at D. Once these line up, the table is in correct location for the cutting of the first tooth in the rack.

As soon as the cutter passes through the tooth being cut the table is tipped, also the lever C, which automatically brings the pointed tooth at end of C out of mesh with the first tooth in series of teeth A. This is a fool-proof arrangement so that the operator cannot damage the complete templet A.

To cut the next tooth the table is moved until the pointer at end of lever C can be placed in mesh with the second tooth in series A; the table is further adjusted until point B lines up with mark D once more, when the second tooth of rack is cut. This is kept up until all the teeth have been completed.

This machine, although only slightly larger than bench size, is very rigidly built, as the illustration will show, it being very necessary that vibration be eliminated. Even the spindle is specially designed, extra long bearings with adjustable features being provided. A single pulley on end of spindle is sufficient for driving purposes.

When cutting pinions on this machine a special dividing head is mounted on the table, this having a large diameter dividing disc, in order to avoid inaccuracies. To further guard against error this disc is notched on the outside diameter and holes are not depended upon. Furthermore, one side of these notches is straight and the other taper, this allowing the grinding of the straight side, if necessary, and guaranteeing that the locating plug goes in the same depth each time as stated previously. The chief point which has been kept in mind has been accuracy, for every mesh produced must pass government inspection. This is an exceptional machine to be made in a shop usually working on standard machine tools, but it goes to show what can be done by co-operation between the management, designing staff and shop.

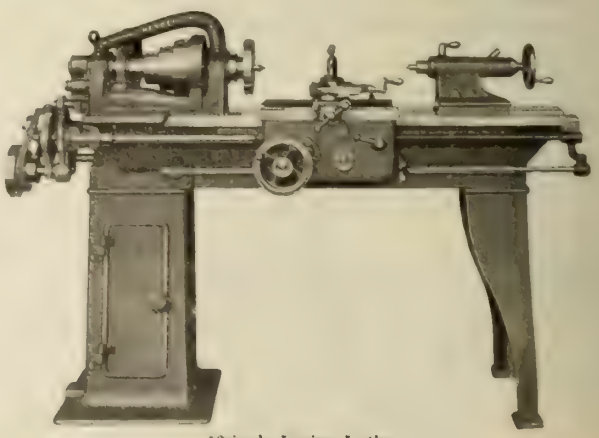


Special Milling Machine.

12-INCH JUNIOR LATHE

A plain-geared engine lathe, especially designed for accurate work in connection with light manufacturing, has recently been placed on the market. The headstock is of improved tie-bar pattern with housings fitted with annular bearings of special metal, having taper bearings for spindle journals. Forward and rear journal bearings are independently adjusted to allow for contraction and expansion of the spindle. Bearings are self-oiled, with oiling rings running in large reservoirs of oil, with provision for catching and returning oil to the reservoirs. The screw cutting is effected through ordinary change gears. Power cross feed and carriage feed are driven by a feed belt over two three-step cones. By the use of change gears the feed belt speed may be modified through a wide range.

This lathe has the regular carriage reverse mechanism for the starting, stopping and reversing of feeds, operated by lever located at the right side of apron.



12-inch Junior Lathe.

allowing both speeds of countershaft to run and drive lathe spindle in one direction, giving a total of sixteen working speeds for spindle. The tailstock spindle is graduated in thirty-seconds. Aprons have double plate construction with safety interlock, preventing simultaneous operations of longitudinal feed and screw cutting. All studs have outboard bearings, and rack pinion is supported either side of its engagement with rack. The inner wall, which carries the outboard bearings, is bolted to front plate and forms an oil pocket for gearing. The beds are made in lengths of 4, 5 and 6 feet, the weight of the five-foot machine being about 1,375 lbs. These lathes are manufactured by the Hendey Machine Co., Torrington, Conn.

CENTERING DEVICE

A special device for center-marking round stock has been placed on the market recently. The hub of the device has a reamed hole through the axis in which is fitted a ground center punch. Sliding jaws are fitted to three equi-distant radial posts that extend out from the hub. A spider with corresponding bosses fits over the hub and is so arranged as to prevent end movement. Connecting rods join the radial bosses to the jaws upon the hub, so that when the bushing is rotated relative to the hub the toggle action of the rods causes the jaws to move simultaneously inward or outward, according to the direction of rotation. After gripping the work in the jaws a light blow with a hammer on the punch puts an indent in the center of the bar. The tool is marketed by the J. A. Finley Co., of Allston, Mass., under the name of the "Duwell" centering device.

1-INCH MICROMETER

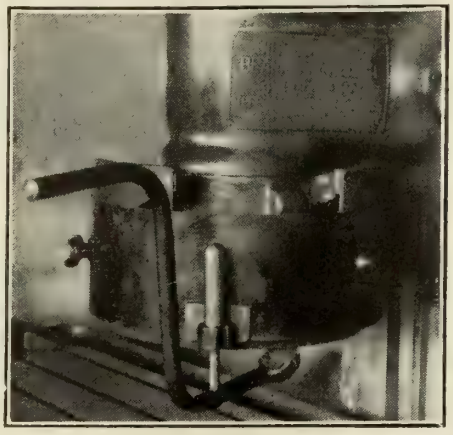
A new one-inch micrometer has been placed on the market by the L. S. Starrett Co. The frame is drop forged and is ribbed to provide added rigidity, and is finished in black enamel. It is claimed to have a longer life due to the fact that the contact points are .270 in. dia. with a screw of .312 in. dia. Decimal equivalents are marked on the thimble. The micrometer can be obtained either with or without a rachet stop.

SELF-GUIDING SCRIBER

A special scriber, particularly adapted to the use of toolmakers has been introduced to the trade. The feature of the tool is the double point, by means of which it is possible to lay out an outline at the bottom of a small, irregular-shaped hole, as in the transferring of shapes of dies to punches and blankholders. One point is sharp while the other is rounded and slightly shorter than the scriber point. In operation the tool is placed in the small hole and then twirled by the thumb and finger, the spring points causing the scriber to follow the outline of the hole. For large holes the regular scriber point is used. The tool is made by the J. A. Finley Co., Allston, Mass.

SAFETY WHEEL DRESSER

A great many operators claim satisfactory results cannot be obtained except by hand method of wheel dressing, but this is unsafe and never advocated. The new style dresser brought out by the Pratt & Whitney Co. for use on their vertical surface grinders gives all the advantages of hand dressing without



Safety wheel dresser.

danger of injury to the operator. It consists of a bracket bolted or riveted to the wheel guard which supports the stem of the dresser. The dressing wheels are held in one end of the device, the bar being bent to fit under the wheel. The other end forms a handle so that the attachment can be easily moved into position. No change in the work and wheel relation is necessary and the device is quick acting and thoroughly efficient. It may be readily applied to grinders now in use and is furnished as regular equipment on new machines.

PIN DRIVE FOR SMALL TOOLS

A line of small tools provided with special holders has recently been offered to the trade. The cutters are made of high-speed steel while alloy steel is used for the holders. The cutters may be provided for a wide range of work, including milling, reaming, drilling, countersinking, etc. The cutter is prevented from turning on the holder by a small pin running lengthwise in a groove. The design provides a positive drive and enables tool to be run accurately, also permitting the use of a small shank. These tools are particularly well adapted to turret operations. They are made by the Hanson Tool and Die Co. of Detroit, Mich.

METAL-PARTS WASHING MACHINE

For the washing of large quantities of metal parts a special machine has been developed. This particular apparatus is capable of taking care of the washing and rinsing, and also the drying if the latter is necessary. The machine is built on the unit principle, the sections being added as required. Formerly the washing and rinsing were performed as two distinct operations. The machine is especially serviceable where a large volume of water is required. The machine will take care of parts 24 x 40 in. in any length up to 16 ft. The work level is 34 in. above the floor. The shell is made of 10-gage steel plate supported by 6-in. channels. The initial chamber is provided with two-arm upper and lower revolving washing units for spraying water on the work, the sprays operating in opposite directions; 1,200 gals. of water per min. is supplied to the nozzles by means of a centrifugal pump operated by a 15 h.p. motor. A 3 h.p. motor is used to drive the pump that distributes 400 gals. of fresh rinse water per hour. When washing small objects, such as stamping and screw machine products, the parts are placed in racks made of wire mesh laid over pressed steel frames. Two 18 x 24 in. racks can be fed into the machine, side by side. They are carried through the machine on a continuous conveyor, so as to pass under both the washing and rinsing sprays. Larger parts can be conveniently handled in the machine. These washers are built and marketed by the Crescent Washing Machine Co., New Rochelle, N. Y.

GEARED-HEAD ENGINE LATHE

A recently developed 24-in. all-geared-head engine lathe equipped with a motor drive, has been placed on the market. With the exception of the main spindle all shafts are fitted with ball bearings, and all headstock gears run in oil. The head is of the selective type and the drive may either be from an overhead shaft or direct from a motor mounted on the top of the headstock. Twelve speeds are possible, using fourteen gears. A friction clutch is incorporated in the main drive pulley, and may be operated from the right hand side of the apron or from a push rod overhead. Provision is made for stopping the spindle quickly. The lead screw half-nuts are provided with a locking device, to prevent their engagement when the feeds are being employed. Accessory attachments may be interchanged with the compound rest. This lathe is manufactured by the Springfield Machine Tool Co., Springfield, Ohio.

PYROMETER FOR MOLTEN METALS

For the purpose of instantly determining the temperature of molten metals, a special pyrometer outfit has recently been placed on the market. The appliance consists of a standard type PA portable meter and a specially constructed thermo-couple, the ends of which are easily removable. When new they are 16 in. in length and may be used until they are reduced to a few inches. They are inserted bare into the molten metal, such as aluminum, babbitt, brass, bronze, copper, etc., and the temperature can be read directly from the meter. The safe limit of temperature is about 2,200 deg. F. The scale is graduated in degrees from 32 to 2,500. The case is made of cast aluminum with a black enamel finish. Twenty feet of flexible cord connects the couple and the meter. These outfits are made by the Hoskins Mfg. Co., Detroit, Mich.

Railways Need Shop Equipment

INDUSTRIES doing business with the railroads seem agreed that there should be a better buying inclination evident in that direction. That they need much new equipment for their shops, even the railroads themselves will admit. In fact, it is declared that requisitions for shop machinery have been made out for some time, but seem to await sanction from some place higher up. A prominent manufacturer who investigated the situation for himself declares that much equipment is needed, and that as soon as conditions are right the order to go ahead will be given. The situation is better than it was one year ago as regards railroad buying. American roads have been heavy purchasers of equipment. Canadian rolling stock was in better shape and proper upkeep was imperative in view of bumper crops. The outlook of the Canadian Locomotive Works at Kingston indicates marked improvement and the impression is gaining ground that with the reorganization completed in connection with the National System, with a clear industrial horizon and the greatly improved general tone, this business will come along.

Coal Men Merge for Economy

MERGER OF bituminous coal interests in Pittsburgh district is announced, involving a score of big operators with normal annual production of eight million tons and assets of $35,000,000. The reasons given for the merger are said to be the elimination of costly duplication in sales, supervision, laboratory, traffic direction and purchase department overhead expense. The new company will be a formidable competitor to the Pittsburgh Coal Company, probably the largest company mining soft coal in the world.

To the consumer of coal it would naturally appear that such mergers should bring about a solution of some of the evils surrounding coal production whereby costs tend upward rather than back toward former levels. During the recent coal strike some facts found prominence with reference to mine operation which did not seem to be generally known and appreciated by the buyer and consumer of coal. One deep-seated problem relates to the fact that there are so many mines and miners in operation that normal requirements may be easily overtaken. Mining does not seem to be conducted on a full-time basis, and hence wages have to be sufficient to carry over the idle workmen and this eventually means peak prices to the consumer. If time and processes will evolve a system whereby the coal industry may become amenable to laws of supply and demand as other industries are, rather than to uneconomic manipulation, then the long-suffering public may be able to regard its fuel bill with less apprehension. The consumer has his part to play in purchasing well in advance of the rush period, and he has now something to steer by in the fact that agreements with the miners run until April 1st next. It remains to be seen whether production will be equal to the enormous demand that must develop during the next seven months.

Select Industries Carefully

MUNICIPALITIES are displaying a wise degree of caution with regard to industries that present themselves for location and probable operation. It is not long ago that a statement appeared in this paper from an industrial commissioner who declared that he had many prospective industries on paper, but that the majority of these were looking for much and offered very little. He pointed out that there were a great many smooth promoters in the field who, if brought to a showdown, had as their ultimate object, some favor that eventually worked back to the pockets of the ratepayers. It seems unfortunate that not a few of these questionable industrial schemes have as their focus the motor car and truck industry, but it will always be the case that wherever prosperity flourishes there will also be found the greatest number of speculative propositions. It is a problem sometimes to sift the good from the bad, but nowadays it must be a clever scheme that gets by the industrial commissioner, the chamber of commerce, the board of trade and the industrial committee of the city council, all of whom are supposed to be keen business men. If fakes are more numerous, the public interest is also more carefully safeguarded, or should be.

Will Industry Stand the Gaff

FOLLOWING the wage advance of twenty cents an hour by the United States Steel Corporation, similar action has been taken by many of the independent companies, and the movement will likely become general in the steel industry.

While it is claimed that independent companies as a rule pay less than the Steel Corporation, the fact is that, during the very strong market that has developed since February last, some independents have been bidding for men, thus tending to disorganize staffs of larger mills. Some independents also attempted premature advances in steel prices, but the attitude of the Corporation reflected a determination to develop a degree of stability and to keep prices on a level that would be free from criticism.

Various motives are said to be behind the advance. It may mean nothing more than an attempt to hold existing staffs. On the other hand it is described as a blow at unionism and the closed shop. Another view delares it to be nothing more than a policy of least resistance against unreasonable and uncombatable labor conditions on one hand, and a desire to make the most of the wave of prosperity on the other. Whether these two will mix remains to be seen.

Machine Tool Demand Shows Railway Buying

List of Equipment Approved for Shop at St. Malo, Quebec—C.P.R. Buys Big Tonnage of British Plate—Wrought Iron Pipe Advances $11 Per Ton—Unwelcome War Prospect—Opinion That Serious Development Would Cause Decided Stiffening in Markets

PRODUCTION IMPROVES BUT DELIVERIES SLOW

STEEL prices still appear to be in the advancing mood, as the changes in wrought iron pipe, plain wire, bars, shapes, plates and sheets, as announced this week from Pittsburgh, would indicate. Wrought iron pipe has advanced $11 per ton, and Canadian mills may shortly make an announcement in kind. Wire mills have advanced their prices $3 a ton, while some of those mills that went out of the market on bars, shapes and plates on account of the coal strike have re-entered at $2.25. This is higher by 25 cents than the steel corporation, but the latter's prices are for shipment at mill convenience, which probably means some months hence. It is evident, however, that the turnover in finished steel is not large. Very little interest is being taken in December or first quarter business. Buyers display lack of interest in late deliveries, but if the feeling developed that prices were advancing, the interest might develop strength. One factor making for higher prices is said to be that mills have many orders still to fill that will bring little, if any, profit, owing to sales having been made when material was low. They feel, therefore, that there is an opportunity at present to make an improved showing.

There has been a sharp increase in ingot production since the end of August as the result of coal mine operation, but car shortage still proves to be a limiting factor. Canadian importers say there has been very little improvement in shipments and that with accumulated business pressing for cars the situation does not seem promising.

An Unwelcome Prospect

There is no doubt that the prospect of war has had an influence on Canadian steel and iron business for the past few days. It is an unwelcome prospect, commanding pause while mental attitude adjusts itself. Should the country's resources in men, material and equipment again have to be mustered, the feeling among business men is that experience has been such as to make splendid mechanical and engineering service available at short notice.

That the railways are adopting a more liberal attitude in their requirements of machine tools is evident from purchases that are being made from time to time. Canadian National Railways recently approved a list of machine tools for their shops at St. Malo, Que. The expenditure, comparatively, was not large, but was one of the most worth-while items coming from this direction in some time. Among machine tool dealers it is said that any serious move toward war will have a stiffening effect on the market.

In iron and steel, prices are firm and the demand shows strength. One dealer declares that if there is as good business until the end of the year as during August, there should be no cause for complaint.

Montreal reports that the pig iron situation grows acute. While indications were that large tonnages of Scotch iron had come into the market, customs records show the tonnage to have been only 2 814. Some foundries are running short and soon will have to consider supplies. Demand for iron and steel is increasing, and stocks are difficult to obtain. British mills are quoting a price that would approximate $1.75 base Pittsburgh, and guarantee shipment two weeks after receipt of order. Large tonnages, however, would be necessary. An order for one hundred tons of British plates was placed by the C.P.R. through a Montreal jobber and no doubt much more business will go in that direction should other more convenient sources fail. The seasonal demand for structural steel is falling off.

Toronto

September 20.

ANY REPORT that would correctly describe the situation in the Toronto market this week cannot overlook the fact that prospect of war in the near East had an effect that was more or less disquieting. The fact that Great Britain had invited her colonies to send contingents, at once established the significance of the situation. Development of bear tendencies in the stock markets indicated an early appreciation of the effect of the war-cloud upon public feeling. It was not a sense of depression, but more of doubt or suspense. Canadians are proudly alert to their place in the Empire and it is not surprising that there was pause while duty developed the direction as to employment of resources at the disposal of the country, should emergency call. Threatening events therefore had an overshadowing effect.

Machine tool dealers were of opinion that should the situation become so pressingly serious as to claim priority of materials and equipment, as in the last war, there could not fail to be a stiffening of the market. There were those who considered such a contingency as most remote, however, and who vigorously discouraged suggestion of this kind, although agreeing that Canadian engineering and mechanical skill was in a splendid condition to serve, after its experience in connection with the world war.

Iron and Steel—Generally speaking the Toronto market was without important feature. Prices are firm but unchanged. Although some advances were announced last week on steel bars, it has developed that the price of $3.40 is not representative. Dealers there are who claim that the psychological moment for a raise has not yet developed. They adhere to the $3.25 quotation, and declare that they prefer to reflect an independent attitude. August, they say, was half as good as it should have been, but twice as good as it used to be, and suggest further that conditions render stability in price more or less preferable. It is a fact, however, that the $3.40 price obtains in certain quarters, as when the hardware trade and small lots feature the demand. The Pittsburgh price is $1.90 to $2.00, while Hamilton is quoting $2.70, a spread at the least of 70 cents, which is quite legitimate.

Sheet markets remain active on the advanced prices as announced one week ago. It is felt that fair-sized stocks have been accumulating throughout the country, and that existing figures represent peak. There are dealers, however, who think otherwise. The fact that the Baldwins have closed their Toronto plant does not seem to indicate any radical development in the market. Competition had developed to such an extent and coal and materials so difficult to obtain that it is felt temporary suspension was the wise course. No credence is placed in the rumor that the company is withdrawing from Canada altogether. In fact, enquiry at the plant brought a denial of this report, but there was some corroboration of the statement that they had expected some assistance by way of the tariff from the government. The plant has been producing black sheets and tin plate. Local quotations:—

Iron bars	3 25	3 40
Steel bars	3 25	3 40
Reinforcing bars	3 25	3 40
Steel hoops		4 50
Tire Steel		3 50
Spring steel	7 00	14 00
Band steel, No. 10 gauge and 3-16 in base		3 90
Small shapes		3 50
Sheets, black, No. 28		5 50
Sheets, blue ann., No. 10		4 50
Canada plates, dull, 52 sheets		5 75
Canada plates, all bright		6 75
Galvanized Sheets, No. 28		6 75

Old Material—"So far as values of old materials are concerned," said the representative of a large house, "it is likely that values will remain just where they are." It is considered that the Canadian

pig iron situation is now likely to improve and that conditions in supplies of old material may become a little easier. However, the market has shown little of the spectacular.

There has been quite a development of strength in the American markets. Heavy melting steel is quoted at $18 to $19, Buffalo, while Pittsburgh prices range from $19.50 to $20. Youngstown quotes $21. Local prices are:—

Copper, light, per 100 lbs.	9 00
Copper, crucible	11 50
Copper, heavy	11 25
Copper Wire	11 25
No. 1 compositon	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 25
Light brass	4 50
Medium brass	6 00
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton.	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine castiron	18 00
Pipe, wrought	7 00

Pig Iron—There is a feeling in the market that the pig iron situation should develop an easier tone now that strikes have been settled and coal more easily available.

But it is pointed out that accumulated orders must necessarily be disposed of before new business can be considered. Although the Toronto office of M. A. Hanna & Co. could give no information on the matter, it is reported that furnaces at Port Colborne are to be blown in shortly. Meanwhile Hamilton furnaces are out and the Algoma plant is on limited production. Improvement in the coal situation, it is feared, is likely to be slow under present priority and embargo systems affecting transportation. Supplies of pig are running low and no relief may be looked for from Scotch furnaces.

Non-Ferrous Metals—This market has developed a firmness recently and although no price advances are reported it is the feeling that any complication threatening war would have a decidedly strengthening effect. New York reports that foreign demand is the sustaining feature of the market. Shipments of four million pounds, during the past week, are recorded, most of this amount going to English and French buyers. Tin is reported as active and a trifle firmer. Zinc stocks are reported to be decreasing and New York reports price advances. Local prices:—

Lake copper	17 75
Electrolytic copper	17 50
Castings, copper	17 00
Tin	37 00
Spelter	8 00
Lead	8 00
Antimony	8 50
Aluminum	21 00

Machine Tools—Some activity is reported in this department as the result, it is said, of the Toronto Exhibition. Sales of equipment for garage purposes, such as cylinder grinders, have been made, and a fairly good general list was O.K.'d for the Canadian National Railways, who are improving the equipment in their shops at St. Malo, Que. This business was distributed to a large extent among Toronto dealers. It is stated that this purchase is the forerunner of a less conservative buying policy on the part of the railways.

Buffalo Forge Co., Kitchener, manufacturers of drying and ventilating equipment, report that although the industrial demand has not been what it should be, there has been a fair amount of municipal buying for schools and other public institutions. Pulp and paper mills have also been active buyers in the present season.

American markets report an increase of $11 per ton on genuine wrought iron pipe, which is used largely in construction work where resistance to corrosion is necessary. Basing discounts have been reduced from 39½ to 34%, a difference of 5½ points, each point meaning $2. Advances in the Canadian market may follow.

Discounts on stove bolts have been reduced by the Steel Company from 70 to 65 and 5.

Montreal

September 20)

ALTHOUGH there is only an average volume of business moving in the iron and steel lines, the local situation is bristling with possibilities. The influences of the coal and iron strike have made themselves very much in evidence. Jobbers are managing to obtain steel in sufficient quantities to take care of the business offering. Prices are firm but remain unchanged. The pig iron situation is acute. Only a small tonnage of Scotch iron is available for sale purposes and prices are advanced. The machine tool market is quiet. Supplies are moving somewhat better than they have been for the past few weeks. The demand for non-ferrous metals during the last ten days has shown a satisfactory increase, quotations remaining stationary. The scrap metal market conditions are improving, especially in some of the ferrous metals.

Iron and Steel.—In spite of the unusual conditions which prevail in the basic steel industries, the local demand has not only been maintained but is increasing. Jobbers have been successful in obtaining the necessary stocks from local or U. S. mills to take care of the demand. Pittsburgh prices for preferred delivery, (three to six weeks' shipment), hover around $2.25 base at mill, while the local mills' more or less nominal quotations are $2.70 base to jobber. All quotations are firm. British mills quote figures that would approximate a quotation of $1.75 base Pittsburgh, and guarantee shipment two weeks after receipt of order. That would mean a local delivery of about six weeks after the mailing of the order. Of course, it is considered undesirable to place orders with British mills unless they are for at least sixty or seventy tons.

During the week the C. P. R. placed an order through a local jobber for approximately one hundred tons of British plates. No doubt an increasing number of requisitions will find their way to British mills if the conditions surrounding the industry on this continent are not soon adjusted. Sheets are in good demand locally, particularly galvanized and blue annealed. Practically all sheets handled locally are of British manufacture. The demand continues to be very good indeed, and quotations are firm. There is always a seasonable autumn demand locally, caused by the fact that consumers always plan to cover their winter requirements before the close of navigation. After the close of navigation the rail haul from St. John, N. B., adds more than seven dollars a ton to the cost at Montreal. Thus the present demand is bound to improve right up until the end of December. It is a certainty that the present firm quotations will be maintained if not increased.

The demand for structural steel is falling off somewhat, as is expected at this season. Merchant bars are moving steadily. Small steel products are moving very well indeed. There have been no price changes during the week. Local jobbers feel that deliveries from U. S. mills will continue to improve gradually, unless the demand that has been throttled for some time past is large enough to cause a big increase in the tonnage required, in which case the mills will be a long time in overtaking the situation. Present quotations are as follows:—

Iron bars, base	3 15 to 3 25
Steel bars, base	3 15 to 3 25
Reinforcing bars, base	3 15 to 3 25
Steel hoops	4 25
Tire steel	3 25 to 3 40
Spring steel	7 00
Band steel, No. 10 gauge and 3-16" base	3 65 3 75
Small shapes	3 40
Sheets, black, No. 28	4 40
Sheets, blue ann., No. 10	4 05
Canada plates, dull, 52 sheets	5 50
Canada Plates, all bright	7 00
Galvanized Sheets, No. 28	6 50

Pig Iron.—Except for a few tons of Scotch pig in stock locally there is not a pound available for sale. Local representatives of Canadian producers state that it is largely speculative as to the length of time the furnaces will remain out-of-blast. The coal supply controls the situation. No new orders can be accepted, although most producers right along are making shipments on old orders. Thus quotations on Canadian pig are only nominal.

Such large tonnages of Scotch iron have been shipped to the United States that, during the week, local agents of the Scotch furnaces were notified that the furnaces were completely booked up to October 15th. No new business could be accepted for shipment before that date. In many cases quotations have been advanced. Official customs records of the port of Montreal show that only 2,814 tons of Scotch pig iron have been imported this season up to September 10th. Some foundries are already running short of iron and are ready to come into the market. Others have their requirements covered for only a short time. Everything points to a very acute situation in the near future. Consumption has

been on the increase and it is only reasonable to suppose that it will continue to increase. Local quotations are as follows:—

Algoma, No. 1, car lots on tracks, nominal quotation	40	80	....
Summerlee, 5-ton lots, warehouse	40	50	....
Summerlee, 30-ton lots, dock	35	00	....
Carron, 30 ton lots	35	00	....
Do., 5 ton lots, ex. warehouse	40	50	....

Machine Tools and Shop Supplies.—Very little change is shown in the machine tool market, which has been extremely quiet for some time past. Only a very few small sales have been made and these are for small machines. Movement in the wood working tools appears to be a little better than that of the iron working tools.

The supply business has been on the up-grade for the last week. The demand for small tools is very fair. Few price changes have been made. All lines seem to be moving very nicely. There slight improvement in the machine shops, which will no doubt be reflected in the sale of supplies showing a further improvement soon.

Non-Ferrous Metals. — During the week there has been a slightly better demand for non-ferrous metals. Inquiries and business are widely distributed over the province. There has been no change in prices during the week. Local quotations are as follows:—

Lake Copper	17	75
Electrolytic Copper	17	50
Castings, Copper	17	25
Tin	35	50
Lead	7	00
Spelter	8	75
Antimony	6	25

Scrap Metals.—The scarcity of pig iron has created a much better demand for heavy cast scrap. Foundries are conserving their supply of pig and are thus mixing more and more scrap. The demand locally is much better than it has been for some months past. Other forms of scrap have increased in value, in sympathy with the present situation. Sales have increased somewhat and the whole situation is a great deal more encouraging to the dealers. The following are local quotations.

Copper, light, per 100 lbs.	9 00
Copper, crucible	11 50
Copper, heavy	11 25
Copper Wire	11 25
No. 1 composition	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 25
Light brass	4 50
Medium brass	6 00
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine cast iron	20 00
Pipe, wrought	7 00
Car wheels	17 00
Steel Axles	15 00
Machine shop turnings	4 00
Stove plate	16 00
Cast boring	4 00

Pittsburg

September 20.

LEADING Iron Company issued a new list on wrought iron pipe, dated September 12, advancing prices 5½ points or about $11 a net ton, the basing discount changing from 39½ to 34 per cent., and all other makers are expected to follow. Steel pipe remains at a basing discount of 68 per cent., and advanced about a month ago.

One independent wire mill advanced its prices $3 a ton about ten days ago and all other independents have since followed, making prices uniform among independents at 2.50c for plain wire and $2.75 for nails. The American Steel & Wire Company continues at 2.35c and $2.60, prices to which it advanced late in August. Such independents as are able to make early shipment find no difficulty at all in making all the sales they wish, at the advance. Probably the majority cannot make very early shipment. One interest cleaned up all its old orders and then closed its wire department on account of shortage of steel in the coal strike. Resuming a couple of weeks ago it is able to make very prompt shipment, say in a fortnight.

Most of the mills that were out of the market on bars, shapes and plates on account of the coal strike, have re-entered. The usual price is 2.25c on all three products. One large independent is quoting shapes, to regular customers, asking 2.15c on bars, but not on plates or shapes, to regular customers, asking 2.25c from chance buyers. The Carnegie prices are understood to remain at 1.90c for bars and 2.00c for shapes and plates. Three or four weeks ago many small orders for prompt plates were going at 2.50c, but there seems to be little business at that price now, and fairly early deliveries could probably be secured at 2.25c. The Carnegie prices are for "shipment at mill convenience," which would probably mean many months hence.

In sheets, the two conservative independent mills that were adhering to the steel corporation's prices, based on 3.35c for common black, have advanced to 3.50c. Other independents are asking from 3.50c to 3.75c. Claims are made that there are many sales on the 3.75c basis, but from the fact that some mills quoting on the 3.50c basis can make shipment in about 30 days the probability is that sales at 3.75c do not roll up much of a tonnage, and are perhaps chiefly in less than carload lots.

The National Association of Sheet and Tin Plate Manufacturers reports August figures as follows, in net tons: Sales, 175,495 tons; production, 228,398 tons; shipments, 218,200 tons; unfilled tonnage, 379,249 tons; finished stock, sold but not shipped, 95,058 tons; in stock, unsold, 19,184 tons. The mills thus reporting comprise about two-thirds of the total in the country, and seem to have had a rated capacity for August of 262,000 tons. Sales, production and shipments all increased from July, while unfilled tonnage decreased 30,000 tons during August, while unshipped tonnage increased 14,000 tons.

Price Trends

The general talk in the trade is that steel prices are in an advancing state, and the items given above support this view, in general, but at the same time the actual concrete advances do not make altogether the showing that would be expected if the market is really a sharply advancing one. The total turnover in the finished steel markets is not large, probably on the whole considerably less than the production, even though production is not much over half of capacity. Jobbers and manufacturing consumers show a strong disposition to buy for early deliveries, say for spot, October or November shipment, while they display very little interest in December or first quarter.

This is the condition. What it means is not so clear. Remarks that forward business is light because mills do not want to sell are not convincing. It may be that buyers' lack of interest in late deliveries is due to their being too busy with present day problems to consider the more distant future, but if they were certain steel prices were going to advance further they would presumably find the time to consider late deliveries. Very likely they feel that prices are too high now, and many mills admit frankly that such is the case. Costs are up by a very considerable margin, but cost increases alone would not warrant 2.25c for plates, shapes and bars when these commodities sold at 1.35c or thereabouts early in the year, or 3.75c for sheets when last year the market dropped for a time to 2.75c.

Increase in Production

One reason why mills are anxious to get as high prices as possible is that they have orders still to fill that will bring little if any profit and in some cases may involve a loss, the material having been sold long ago at much lower prices, while it must now be made when costs are much higher. The mills may feel that they should obtain all they can while steel is scarce even though the prices are too high to justify a long buying movement being based on them.

Steel ingot production at the end of August was down to about 50 per cent. of capacity or about 26,000,000 tons a year, having been at between 70 and 75 per cent. in June. Since the end of August there has been a sharp increase in production, perhaps to a 60 per cent. rate. On account of the particular circumstances existing, it does not follow that further increases, at the same rate, are to occur. The increase thus far has been due chiefly to steel interests getting their union coal mines in operation, the U.M.W. wage scale being signed, and promptly establishing a movement to their by-product coke plants. Further increases would have to come chiefly from there being more coal and coke from the Connellsville region, where transportation has already become the limiting factor, and by purchases of coal in the open market, when the distribution of purchased coal is almost completely controlled by priorities, in which the steel industry has no standing.

Connellsville coke is quoted at $11 to $11.50 for furnace and $12.50 to $13 for foundry. Offerings of furnace coke have not been sufficient to justify a furnace trying to gather together enough for an operation. In the past week car shortage has prevented full shipments being made

on contract and offerings are likely to be less in the next few days.

Pig iron remains quotable at $34 for Bessemer, $30 for basic and $35.50 for foundry, valley basis. These figures are not well supported, transactions being very light. It is held that most consumers could not afford to pay these prices, unless they get further advances in their finished products. Recent predictions that pig iron would advance to $40 or $50 have become unpopular.

The Steel Corporation has announced that it will book rail orders, for shipment to July 1, 1923, at the old price of $40 a gross ton, up to October 1, when the price will go to $43. It is a question how much tonnage this move will bring into the market.

FOR MERITORIOUS SERVICE

In C. P. R. educational bulletin No. 216, the following employees are mentioned for meritorious service:

E. T. Gauthier, agent, Cartier, 10 merit marks, for interest taken in arranging diversion of car, at request of shippers, when car had already passed his station, thus saving shippers much inconvenience and possible loss.

J. E. O'Neil, ticket clerk, North Bay, 10 merit marks for detecting that commercial traveler's certificate was being used by other person than owner and arranging to have same lifted.

A. O. Lake, conductor, Schreiber, 5 merit marks, for removing tree which had fallen on telegraph wires during storm.

G. Porter, engineer, Sudbury, 5 merit marks, for attending to hot journal on dead engine traveling on his train, enabling engine to be taken through to terminal.

J. F. Downey, operator, Pays Plat, 5 merit marks, for repairing telegraph wire when not on duty.

S. N. Retty, trainman, Chapleau, 5 merit marks, for firing engine over part of sub-division when fireman was unable to do so on account of sickness.

O. G. McDonald, trainman, MacTier, 5 merit marks, Paul Snob, trainman, Schrieber, 5 merit marks.

C. A. Parfit, trainman, North Bay, 5 merit marks for detecting broken arch bar on car when train was in motion, avoiding possible accident.

The present car shortage makes imperative the elimination of all delays to cars in transit and while being unloaded at destination.

Victoria, B. C.—A conference of Imperial Government officials, British steel manufacturers, Canadian government and the British Columbia cabinet ministers, will be held in London next month in connection with the proposed construction of a $12,000,000 steel plant on the British Columbia coast, according to an announcement made here. The project, it is claimed, is being backed by the three Governments.

C.N.R. BUYS MACHINERY FOR SHOPS IN EAST

Toronto.—By making extensive purchases for shops at St. Malo, Quebec, and Moncton, N. B., the Canadian National Railways have started a buying movement which is regarded in machine tool circles as long overdue. The St. Malo list follows:

One No. 2 Brown-Sharpe surface grinder, one No. 2A Brown-Sharpe universal milling machine, one electric drill, one funnel former, three chain blocks, one pneumatic molding sand rammer, one slip-roll forming machine, one No. 224 combined shear and punch, one No. 2 magnetic chuck, one No. 2 spindle pattern centering machine, one high-speed power hack saw, one portable boring bar with motor, one portable oil rivet forge, four one-ton jib cranes, two half-ton jib cranes, a one-ton air hoist, three geared drills with motor drive, small turner with stand complete, one LeBlond heavy duty production, one hairpin loop armature coil winder and spreader, one coil-winding lathe head, one model C turbine air planer, one pneumatic punch, one emery-wheel dresser, one Davis expansion boring tool, four pneumatic chipping hammers, four pneumatic drills, two pneumatic grinders, one single bar shearing machine, one Bertram special crank pin turning and quartering machine, two C. M. C. quick-change gear engine lathes.

For the Moncton, N. B., shop the list included two No. 13 crucible furnaces (Stewart); one combined shearing and hot punching machine; one 100-ton hydraulic banding press; one 100-ton spring stripping press.

ACUTE CAR SHORTAGE MAY SOON DEVELOP

Montreal.—Throughout the local shops that depend more or less upon the railways for their business, there exists a feeling that the Canadian railways have for sometime past been neglecting their equipment to such an extent that unless they do considerable buying an acute car shortage will develop. This is also more or less true of the motive power departments. Some state that the movement of the Western crop will tax the capacity of the railroads to the utmost and feel that a crisis will develop before the season of navigation on the lakes is closed.

Among the companies depending more or less on the railroads for their business is the Canadian Car & Foundry Co. This company is at present doing practically nothing, having faced the dullest period since the inception of the company, according to one of its executive officers. The sum total of the business on the company's books at present is represented by the order for the Toronto Transportation Company for 150 cars which was mentioned in these columns some weeks ago. The company has continued to quote on more or less work but very little business has materialized from these quotations. The last large order handled by the company was that for the Russian government which was taken care of about one year ago. It is believed by this firm that they can successfully market their products in various parts of the Empire and from time to time as these countries come into the market for equipment they intend to bid on the business. They feel that there is a particularly fertile field in India and the only fear entertained by the local firm is that they would have difficulty in competing with English builders. Car shops, generally speaking, in the United States have experienced quite a revival of business in the last few months and being familiar with the conditions on Canadian roads it is only reasonable for the firm to suppose that they will be receiving orders in the very near future. At present they feel that Canadian National Railway will not do much until the new president, general manager and board of directors are definitely decided upon. However there promises to be an early settlement in this connection and business will no doubt be forthcoming in the near future. In considering the C. P. R., the firm is of the opinion that the C. P. R. have never been in the habit of letting their equipment run down very badly, but they do state, that during the past few years, which have been exceptional, it would not be surprising to learn that they too could do with considerable new equipment.

It is believed that the situation will be brought to a crisis during the next few months when the movement of the large Western grain crop is in progress and the shortage of cars that exists at that time will be the means of bringing the railroads into the market. It is known that in anticipation of the movement of grain a large number of cars have been moved west of the Great Lakes and in a great many quarters it is felt that for this reason a shortage in the East may result.

OIL COMPANY BUYING MACHINERY

In connection with their equipment plans for their machine shop at the proposed Calgary plant, the Imperial Oil Co., Toronto, are calling for tenders on a list of tools, including lathes, planers, grinders and other items necessary in making oil refinery repairs.

The munitions plant of the U. S. Government at Lachine, Que., was early this month sold at auction by Charles Gerth, New York auctioneer. The figure realized was $32,700, the purchaser being Silvio W. Marizzano, managing director of the Saxonia Fruit Preserving Co. of Montreal. Mr. Gerth and his assistants made an effort to dispose of the U. S. plant in Montreal, occupied by the Peter Lyall Construction Co. during the later part of the war, but the highest bid of $292,500 was not accepted. The estimated value of the property is above $1,500,000. The plant is still for sale.

News From the Industrial Field

Stratford city assessor reports an increase of 600 in population. The official return shows 18,244.

Calgary is to have a $2,500,000 oil refinery. The city has encouraged the Imperial Oil Company in the matter by granting a fixed assessment of $250,000 for 20 years.

Makers of dies used in the manufacture of motor car bodies report demand for requirements on car designs for next year. Some radical changes are predicted in certain models.

Employment service figures show that during July the index figure rose from 91.1 at the end of June to 93.1 and that 754,533 people were actually at work July 31, out of an aggregate pay roll of 769,306. The number of concerns reporting was 6,305.

Employment agencies report a very strong demand for men for the lumbering camps. Preparations for a large cut this winter are being made. Wages range from $30 to $35 monthly, and board.

Re-opening early in July of railway car shops, temporarily closed in June, caused an improvement in the labor situation, but an increase was also evident in transportation, railway and building construction as well as in sawmills and other branches of the manufacturing industries.

Tillsonburg may have an industry engaged in manufacture of fire engines and tractors. Efforts are being made to sell $25,000 worth of preferred stock in the town. Another concern wants the town to supply a building 100 x 50 in which to manufacture a staple article.

Two new compressors are being installed at the Strange st. pumping station, Kitchener. The new equipment costs $21,000 and delivery was delayed a month because of the fact that the steamer "Manchester" on which they were shipped collided with an iceberg. The compressors are eight feet high and seven feet wide.

Engineering & Machine Works, of Canada, St. Catharines, report that conditions show steady improvement. The factory at present is well employed on work that indicates a better feeling generally. Among other jobs in process is the building of two boilers, one 14 feet dia. and the other 10 feet dia., for Great Lakes Transportation Co., the Playfair interests, who are rebuilding two of their ships. One hundred and twenty-five hands are employed at present and the coal situation is not such as to cause anxiety.

The steel contract for the new $500,000 building for the Knights of Columbus in Montreal has been awarded to the Phoenix Bridge and Iron Works of Montreal.

Fraser S. Keith, general secretary of the Engineering Institute of Canada, was in Port Arthur recently for the purpose of organizing a branch of the society at the head of the lakes.

Sherbrooke, Que.—Operations have commenced at the plant of the Manganese and Steel Foundry, and the mill is now turning out castings. The furnace is capable of handling one ton at a heat and three heats can be run in a day. This capacity is expected to be reached within the course of the next few weeks, as the company has a number of excellent orders booked up, and prospects are stated to be bright.

John G. Abraham, general sales manager of the Beldam Asbestos Co., has just returned from an extensive trip through the West. Mr. Abraham reports splendid outlook for his products, and likewise announced that he had made arrangements for his firm to act as general distributors for the John Crane Metallic Packing Co., and certain other specialties. The John Crane Metallic packing will be manufactured in Toronto as soon as satisfactory arrangements can be made.

Winnipeg, Man.—After a careful survey of the reports received from agents throughout the West, it is estimated that this year's western crop will approximate 317,000,000 bushels of wheat, according to the weekly crop report of the Agricultural Department of the Canadian Pacific Railway. Cutting is general in the Prairie Provinces. Reports indicate that the Western crop generally is turning out well. Even in areas where poor yields were looked for the conditions have proved better than anticipated.

Montreal.—The Brockville factory of Eugene Phillips Electrical Works, will be completed about October 15th. This factory will roll copper rods entirely, and will be the only copper rod rolling mill in Canada. The firm have installed over three hundred and fifty thousand dollars worth of equipment. This includes not only the mill machinery but their own transformer station, pumping house, etc. The factory is situated in the western section of the town, on the river bank. It is expected that about forty men will be employed from the start. The prospects, as far as they can be foretold at the moment, are that the mill will operate full time from the start.

Atlas Construction Co., of Montreal, has been awarded the contract for extensions to the Alexandra Pier in the Harbor of Montreal. The cost will approximate $400,000.

Winnipeg, Man.—Some idea of the high grade of this year's wheat crop can be gained from the fact that out of 246 cars received here in one day 159 graded No. 1 Northern, 13 No. 2 Northern and 8 No. 3 Northern.

McDougall and McNeill of Vancouver, B. C., have secured the general contract for the erection of a pulp and paper mill for the Wigwam Pulp and Paper Co., of Elko, B. C. The approximate cost will be $3,000,000.

Calgary, Alberta.—A $2,500,000 oil refinery plant will be located here by the Imperial Oil Co., on a site comprising 108 acres now waste land in the eastern part of the city. The agreement between the city and the Company has been approved, and it is said that the construction of the new plant will employ from 300 to 500 men continuously from six to eight months.

McKinnon Industries, St. Catharines, report that they are fairly busy in all departments. Activity in production of gears for motor cars has reflected the improvement in the motor industry. The foundry is also engaged in auto work and railway castings, while in hardware lines improving demand is noted from the West where stock levels are low. It is not anticipated that steel at present prices will have much effect upon buying, but abnormal tendencies might cause a return to higher auto prices.

Brandon, Man.—There is absolutely no unemployment in this city at the present time. In fact there has been an insistent call for farm labor and there is no excuse for any person being out of work here this month. It is estimated that the farmers in the Brandon district are carrying out their harvest operations about 400 men short of the actual need. Farmers and employment agents could not interest eastern harvesters to stop over here, the harvesters preferring to go as far west as their ticket will take them, although this district was paying equally as good wages as points farther west. All local industries are well employed, and activities in all lines are much better and brighter than a year ago. Crop prospects are excellent here for a bumper yield, and consequently there is a feeling of optimism that is booming business along. There has been a decided improvement in business during the last two or three months, which speaks for prosperity this fall.

Campbellton, N. B.—The shipping season from this port has established a record for recent years and a similar activity is evidenced as far as Bathurst and the Miramichi Valley. Most of the steamers at the port have been engaged in clearing lumber held during the war period, but further opportunities for the lumber industry are confidently expected to follow.

Vancouver, B. C.—Vancouver is beginning to realize that more grain elevators are needed, if the port is to hold the grain export trade secured last year. Between September 1st, 1921, and the present 7,552,044 bushels have been shipped from the port, compared with 460,000 bushels the previous twelve months. To carry away this amount of grain 80 ships, each taking 3,000 tons, must be employed. The elevator at Vancouver will hold 1,250,000 bushels, 37,500 tons, or roughly 12½ shiploads.

Elko, B. C.—Financed by American and Canadian capital, with Canadians in the majority on the directorate, a $13,000,000 newsprint plant is shortly to be erected at Elko, near Nelson. The edifice will be built in three units, one a year, and the project will employ 1,000 men in construction and when completed 3,000 in operation. The output per unit will be 100 tons of newsprint per day or 300 tons from the three units. It is estimated that the limits which have been secured will supply raw material sufficient for thirty years' production.

Ottawa.—Large property holdings in Low township, along the shores of the Gatineau River, including the Riparian rights to the Parigan Falls, have been acquired by the Hull Electric Company, which intends establishing next year a hydro-electric power plant with an ultimate capacity of 150,000 horse-power. The cost of construction, it is said, would approximate $10,000,000. It is estimated that it would take about two years to complete the plant, including a large viaduct and dam and that employment would be found for about one thousand residents of this district.

Montreal.—Messrs. Jones & Glassco, Montreal and Toronto, have recently accepted the Canadian agency for the Unchokeable Pump, Limited, of London, England. This pump is a specially designed unit of the centrifugal type and it is guaranteed to pump with its patent impeller the following materials, when they are mixed with a nominal quantity of water—fibre, grit, tailings, flushings, ashes, sand, tan, sewage, grain, mud and pulp. The design of the pump is such that it depends on nothing but the impeller to deal with the solids and the pump will swallow anything capable of passing through the suction opening. The pumps are standardized and absolutely interchangeable. It is stated that the pump has successfully demonstrated its ability to handle solids of a coarse and bulky nature in a manner that has never been done before by a pump.

Toronto.—Extension work to cost more than $2,000,000 has been planned by the Bell Telephone Co. in Toronto alone during the coming year, and it is expected that an average of $2,500,000 will be spent during the next five years to keep up with the demand. This city now has a total of 110,000 subscribers, roughly 30 per cent. of the company's list, and there are at the present time nearly 10,000 waiting for connections.

The closing down of the Ford plants, supposedly as an industrial strike against the excessive coal prices, has become effective, and in consequence approximately 73,000 men in the Detroit district are out of work. The situation is still further aggravated by the fact that something like 30,000 employees of other concerns are affected by this move, these latter being engaged in the production of parts used in the construction of Ford cars.

Montreal.—A new grain elevator is to be built at Tarte Pier, costing $2,347,000, with an initial capacity of 2,000,000 bushels, to be ultimately increased to 8,000,000 bushels, according to the announcement of the Minister of Marine and Fisheries. Other improvements to the harbor include extension of piers and railways, improvement of channel and construction of a new bridge, are to cost in excess of four and a half million dollars.

Niagara Falls, Ont., Chamber of Commerce reports a number of new industries in immediate prospect. The Dominion Insulator Company, manufacturers of insulators and other electrical accessories are completing their factory; the Glen Motor Car Co., an assembly proposition, will locate there and negotiations are concluding with a motor car accessory and machine company. The Robert Manufacturing Co., Lockport, N. Y., makers of knives for paper cutting in paper mills, are building a new steel and concrete factory.

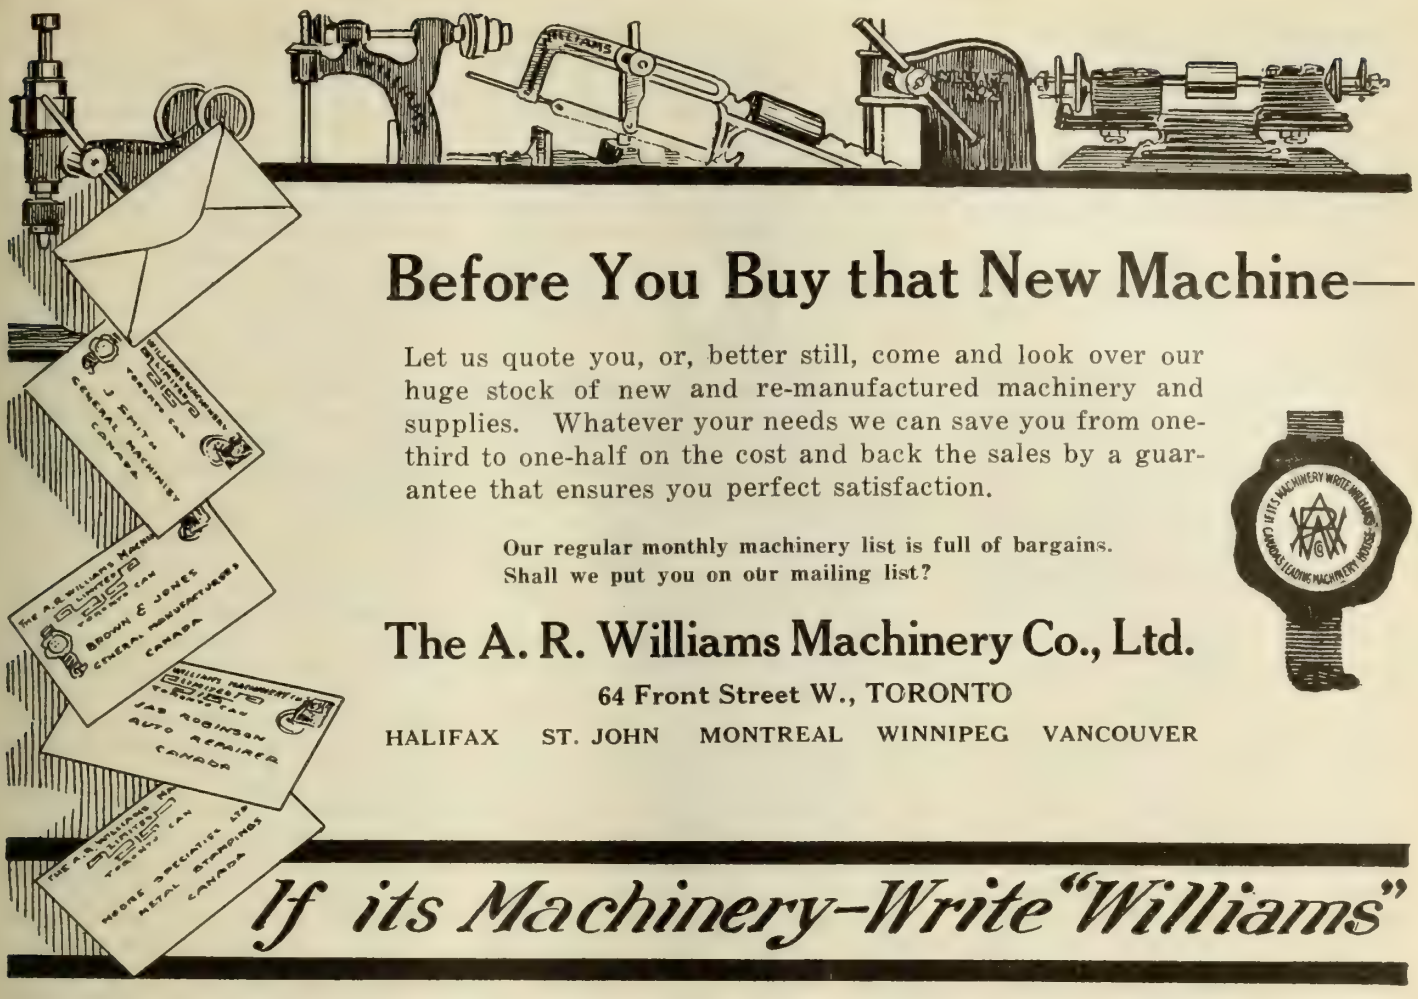
Following the action of the United States in putting shingles on the free list there is a possibility of the McMasters Shingle Co., one of the largest shingle manufacturers of Washington and Oregon, establishing extensive plants in British Columbia. "The situation is very serious," stated John McMasters, "as the output in our American plants last year was approximately seven billion shingles, and that of British Columbia about two billion. But the recent inimical action of the conference committee on tariff will undoubtedly reverse these outputs."

Montreal.—Private advices received on September 12th by several prominent coal dealers here, indicate that this city and New York will be the first to receive considerable consignments of anthracite coal from Pennsylvania district. September 18th is stated to be the day on which Montreal will receive its first cargo which is coming down by water from Oswego, N. Y. It is understood that a great deal of Montreal's supply of anthracite coal, which will be received in the next few months, will be water borne from lake ports. The car borne coal will start a little later but at this season there will be a big demand on the various water routes which lead to the Lachine Canal. It is stated that Montreal occupies a very important place in the Pennsylvania market as about 25 per cent. of the anthracite coal from these mines, purchased in Canada, comes to Montreal. F. L. Wanklyn, the Quebec fuel commissioner, produced recently before the Coal Dealers' Association letters and cables each containing offers of coal ranging as high as 30,000 tons a month during the navigation season. Thus should the coal strike have continued for any greater length of time it is shown without doubt that emergency supplies of coal could have been obtained.

COPPER AGAIN USED IN CARS

Copper, brass and bronze are returning to service in automobile construction. During war years substitutes had to be used, for these materials were not available for non-essential industries. This year according to a statement issued by the Copper and Brass Research Association, something like fifty thousand tons of copper will be used in the motor car industry, which is something like fifteen thousand tons more than last year. During the buyers' strike in 1920 the demand for cars dwindled, and in an effort to revive sales, manufacturer vied with manufacturer in successive price cuts. Under insistent pressure to lower costs, automobile manufacturers turned their attention first to the more expensive metal, copper, and carried still further the principle of substitution, first generally established during the war years. Substitution took many forms, among them being sheet-iron water tanks in place of brass or copper; malleable or cast-iron water line fittings in place of brass; cast-iron carburetor bowls in place of brass; die-cast babbitt main bearings and crank pin bearings in place of bronze-backed babbitt. Other substitutions were cast iron bushings in place of bronze in camshaft bearings, rocker arm bearings, spring eyes, shackle bolts, brake equalizers, etc. (in many cases, there are no bushings at all); cut-steel or aluminum alloy small gears, for pump drive, timer shaft, etc.; cast iron water-pump casing and impeller in place of bronze or brass; aluminum or pressed steel hub caps in place of nickeled brass; aluminum, enameled iron, or sherardized steel windshield trim, body trim, hardware and hood trim; steel latches in place of brass; steel screws, nuts and bolts in place of brass; malleable or cast iron special fittings such as caps, covers, plugs, glands, control links, in place of cast brass.

Grinding wheel spindles should be of sufficient length to permit of the nut being drawn up flush with spindle end.



Before You Buy that New Machine—
Let us quote you, or, better still, come and look over our huge stock of new and re-manufactured machinery and supplies. Whatever your needs we can save you from one-third to one-half on the cost and back the sales by a guarantee that ensures you perfect satisfaction.
Our regular monthly machinery list is full of bargains.

DIFFICULT YEAR FOR STEEL INDUSTRY

By the report of the Lake Superior Corporation's operations for the year ending June 30, 1922, it is shown that the net earnings were $330,00.80, to which should be added $734,814.26 brought forward as a balance for last year. When provision had been made for interest on bonds and for bank advances, amounting to $1,410,478.88, the sum of $87,703.81 had been set aside for depreciation, and $445.40 had been provided for income tax, there was a deficit of $763,813.83 carried forward by all companies. The net earnings of all the subsidiary companies in the preceding year amounted to $1,541,293.32, a decrease of $1,211,292.42.

The past year was a very difficult one in the iron and steel industry in Canada, as elsewhere, and the Algoma Steel Company felt to the full the effects of the continued depression. Steel plant operations were seriously curtailed, and decreases shown in both output and earnings. Rail orders received were not sufficient to keep the rail mill operating full time. The mill was operating fifty per cent. of capacity for 194 days, and was closed down 67 days. For the balance of the year the mill was in full operation.

During the first quarter of the fiscal year under review it became necessary to make a further reduction in prices of steel products, and in order to meet this, economies had to be effected in various directions. There was very little buying in rails and other products by the Canadian railways, but a fair proportion was received of the business offered. Rail production for the year was 155,764 tons, as compared with 201,312 tons in 1921. The pig iron shipments were 64,189 tons, as compared with 105,619 tons in 1921. Orders on hand at June 30th were sufficient to keep the rail mill in full operation until September 5th, and the merchant mill until August 31st. It is expected that further rail orders will be received in the fall for winter rolling. The possibility of the coal and railroad strikes in the United States affecting the company's importations of coal and ore for the coming winter, however, is causing considerable concern at the present time.

The tonnage of the Algoma Steel Corporation, as compared with the preceding year, was as follows:—

	1920-21	1921-22
Coal imported	841,983	468,534
Ore imported	420,830	298,740
Limestone produced	235,399	164,218
Coke produced	429,041	273,007
Pig iron produced	362,805	246,779
Steel ingots produced	327,906	230,237
Steel products	255,209	173,012

The complete cessation of operations of the International Nickel Company and other industrial concerns upon which the Algoma Eastern Railway Company is dependent for its principal traffic, was reflected in the earnings of the company. The reduction in the tonnage of mining and other products hauled, as compared with the previous year, was approximately 1,000,000 tons. As a result the company was not in a position to pay the half year's interest on its first mortgage bonds, which was due March 1st, 1922. It is understood that the mining, smelting and refining operations of the International Nickel will be resumed about Sept. 1st, 1922, on a basis which will furnish ore traffic to the railway of approximately 50,000 tons per month. Coal, coke, quartz and other mining supplies will be shipped in proportion.

More than 26,000 strikes have disturbed industrial America during the past decade, it is estimated. More than 60% of the strikes for the past ten years have taken place in the States that lie north of the Ohio and east of the Mississippi; about 10% of them in territory to the south of the Ohio and east of the Mississippi; and the rest in the West.

CANADA'S CHANCE IN SOUTH AFRICAN TRADE

A trade commission report on South Africa's import trade last year, reveals some interesting figures as to Canadian and American exports in that direction. Dealing with machinery and engineering equipment the report states:

Cranes.—In 1921 total imports were valued at £89,978, of which Canada is credited with £19,885, and the United States with £15,250.

Machine tools.—Of the total import valued at £22,088 during 1921, machine tools to the value of £614 were supplied by Canada, while the share of the United States was £9,821.

Machinery, mining.—Total imports during 1921 were £940,535 as compared with £765,986 in 1913. During 1913 Canada supplied mining machinery to the value of £166, whereas in 1921 her share was £2,986. Imports from the United States were valued at £161,191 in 1913 and £347,001 in 1921.

Machinery, printing and bookbinding.—Total value of imports had risen in 1921 to a value of £165,856 when compared with imports of 1913 valued at £45,866. Of these totals, Canada is credited with £11 in 1921 and £91 in 1913, and the United States with £81,779 in 1921 and £6,457 in 1913.

Pumps.—Total value of imports in 1921 was £150,230, of which Canada is credited with £31 and the United States with £37,819. Canada's share was nil in 1913, when the United States supplied pumps to a value of £30,888 in a total import of £115,861 from all countries.

Windmills.—The total value of imports in 1921 was £117,529, and in 1913, £79,771. Canada took no share in such imports in 1913, but is credited with £1,023 in 1921. The United States supplied windmills to the value of £96,110 in 1921 and £60,899 in 1913.

Canadian engineering plants which have already interested themselves in South African trade, and prospective exporters, will be interested in knowing that in the few instances of increased imports into South Africa last year, machinery leads. These are mining, printing, water-boring, and manufacturing machinery. Both manufacturing and mining machinery show value of import of over £2,000,000.

In addition to such imports as are indicated above, there are supplies for the South African Government Stores such as air compressors, £3,103; boilers, £69,164; cranes £111,578; elevators and lifts, £8,619; engines, tractors and steam rollers, £5,982; machine tools, £17,986; manufacturing machinery £88,691; printing and bookbinding machinery, £11,148; pumps, £10,645; sawing machinery, £5,681; water-boring machinery, £85,343; machinery, all other, £142,305. The ability of Canadian engineering firms for competition in overseas fields is best known to themselves but if it is only the possibilities that are required to induce them to make an effort, surely the figures indicated showing general and government imports will warrant an endeavor by representation on the spot.

Electrical material-batteries, primary.—Total value of imports in 1921 was £29,823, of which Canada supplied £218 as against £11,047 from the United States.

Cables and wires.—Total value of imports was £394,470 in 1921 as compared with £250,669 in 1913. Canada supplied cable and wires to the value of £33 in 1921 and £64 in 1913, while the United States is credited with £14,319 and £29,518 in 1913 and in 1921 respectively.

Quite a number of entries under the heading of electrical machinery and material show increase of imports over 1920. All through the past year the writer has heard of the wonderful purchases made from Germany of electrical material, but it is only in "incandescent lamps" and "material n.o.d." that she figures to any extent (incandescent lamps, £3,133; "material n.o.d.," £14,010). However, some contracts placed for delivery this year if completed will bring them well back to their 1914 supply.

Now that two of the leading municipalities are in a position to sell power freely there should be a much larger sale for electrical household utensils. The position in regard to fixtures is a little better than it has been in the past, but the selling of any but drop-lights is still very small comparatively.

Railway material, n.o.d.—Total imports under this heading were valued at £40,373 in 1921 as against £35,912 in 1913. Canada's share was nil in 1913, but in 1921 she is credited with shipments to the value of £186. Imports from the United States totalled £4,638 in 1921 and £304 in 1913.

Tramway material, rolling stock.—Total imports in 1921 were valued at £55,063 as against £28,403 in 1913 (Canada, 1913, nil; 1921, £46. United States, 1913, £11,794; 1921, £41,006).

Tramway material, all other except sleepers.—Total imports were valued at £37,425 in 1921 and £16,841 in 1913 (Canada, 1913, nil; 1921, £3. United States 1913, £5,141; 1921, £12,586).

There is no record of imports from Canada of light rails and accessories for industrial purposes, rails, locomotives, rolling stock, or tramway rails, but the United States is credited with large shipments under all these headings.

Rejecting a bid of $292,500 for the Peter Lyall munitions plant, at Longue Pointe, Montreal, recently, the auctioneer declared it to be ridiculous and added, "If I went back to Washington with $292,500 for this property, they would put me and my children and my grandchildren in the penitentiary for life."

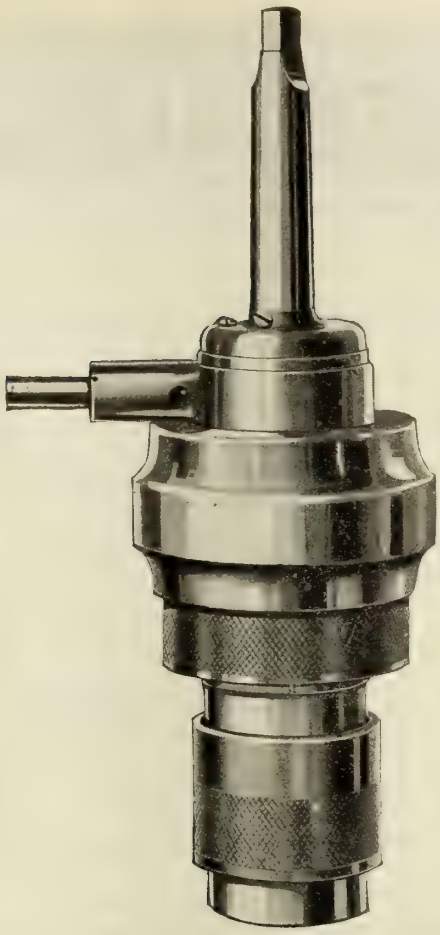
Make a Time Study of Stopping and Starting Your Drilling Machine to Change Tools.



Then Compare the Steady Saving When Using a Jarvis High Speed Tapping Device With Quick Change Chuck.

With the ordinary equipment, the machine must be repeatedly brought to full stop in shifting tools, where there are a number of different operations in a radial drill or heavy duty drilling machine.

ALL THIS LOST TIME IS CONSERVED

BY THE JARVIS TAPPING DEVICES WITH QUICK CHANGE CHUCKS

Engine Cylinder Heads are drilled, tapped and studs set, while other parts are drilled, reamed, counterbored and tapped or spot-faced without a stop.

Jarvis Tapping Devices with Quick Change Chuck can be used on any Radial Drill job that calls for tapping or stud setting. One manufacturer taps a number of different size holes in a wall-radial drill without stopping the machine.

Different style devices fit them particularly for the requirements of the work in hand.

Style S is arranged for heavy work, such as Engine and Motor Castings, Machinery and Automobile Parts

Sometimes a job requires a positive drive with no reverse. Then the Jarvis Style R Device, with Locking Ring, is Used

Any standard Jarvis Product will be sent on trial to Reliable Concerns. Jarvis High Speed Tapping Devices and Quick Change Chucks and Collets are carried solely by the Geometric Tool Company.

DO YOU MISS IMPORTANT NEWS?

WE read the newspapers of Canada and the United States as a business. We can supply you with valuable news on any subject, whether you are interested as a manufacturer, wholesaler, retailer, advertiser, editor, farmer, or politician. We send you these original clippings, which keep you posted on current events, changes in business, prices, construction news or any special information you wish us to gather. This service costs you little and is valuable to any business. Write for prices and name your subject. Canadian Press Clipping Service, 143-153 University Ave., Toronto.

Effective Co-operation

THE three newspapers you see illustrated here belong to the MacLean Technical Group.

If you are a manufacturer of equipment that can be used in machine shops, metalworking plants, power plants, or foundries, one or all of these papers can give you effective cooperation in increasing sales.

Tell the consumer about your products in the columns of these publications. The men who buy industrial equipment read them. Your products may have advantages over other products of their kind.

Tell the consumer what they are. Create a desire in his mind to buy your lines when ordering from the dealer.

An effective message in MacLean Technical Newspapers will prove effective cooperation for the promotion of sales, and the group you can use to greatest advantage includes:

CANADIAN MACHINERY
AND MANUFACTURING NEWS

POWER HOUSE

CANADIAN FOUNDRYMAN
AND METAL INDUSTRY NEWS

Canadian Machinery serves the iron and steel and general metal working industries.

Power House serves steam, electrical, water and gas power plants.

Canadian Foundryman serves the grey iron, steel and non-ferrous foundries.

Each of these papers covers their respective fields almost exclusively. They are "Canadian National" in scope and are read by the men you are anxious to reach—proprietors, managers, superintendents, purchasing agents and foremen. Attract the attention of these men with a strong appeal in their favorite technical newspaper—the MacLean service staff will assist you.

NORTON

Alundum Crystolon

Have You Figured Your Real Grinding Costs?

For Example:

Grinding Wheel No. 1—Lasts 3 days
Grinding Wheel No. 2—Lasts 4 days

and

Grinding Wheel No. 1—Grinds 2,000 pieces
Grinding Wheel No. 2—Grinds 2,300 pieces
The Wheel cost is the same: $11.90
The Labor cost is the same per day: $4.50
The burden or overhead charged to the machine is the same per day: $6.75

Grinding Costs

WHEEL No. 1		WHEEL No. 2	
Wheel	$11.90	Wheel	$11.90
Labor (3 days)	13.50	Labor (4 days)	18.00
Burden (3 days)	19.25	Burden (4 days)	27.00
Total	$44.65	Total	$56.90
for 2,000 pieces.		for 2,300 pieces.	
Or $.022 per piece.		Or $.025 per piece.	

Wheel No. 2 costs the same as No. 1.
Wheel No. 2 lasts 33 1-3% longer than No. 1.
Wheel No. 2 grinds 15% more pieces than No. 1.

But
Wheel No. 2 Shows a Total or Unit Grinding Cost 13½% more than No. 1

Why?

The answer is **CUTTING SPEED.** There's a lot of difference between the **CUTTING SPEED** of these two grinding wheels. It isn't only the first cost of the wheel; it isn't only the number of hours the wheel is in service; it isn't only the total production from the wheel while it is in service; **IT IS** the **production** per hour. That's the real test.

There's a Norton ALUNDUM or Norton CRYSTOLON wheel that will give YOU maximum production per hour. Are you using it?

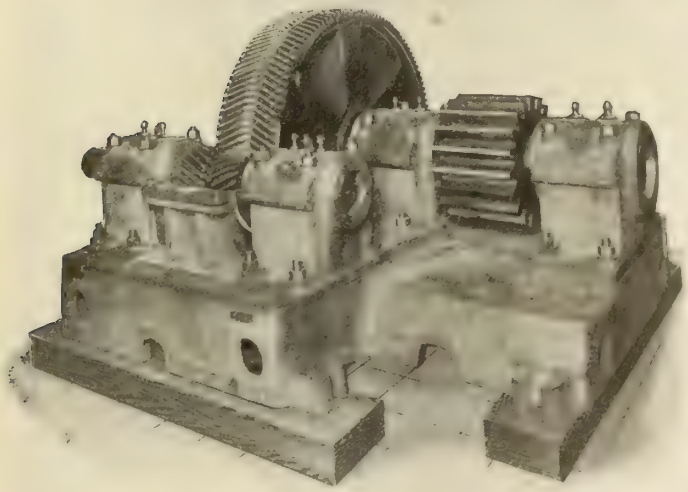
Double Helical Gears



Heavy Mill Drive

GEAR DATA FOR YOUR NOTE BOOK

Cut this out--more coming later.

Standard helix angle—23 deg. Diametral pitch used up to 1 1/4 d.p. Above that, circular pitch is usual. Tooth form, 20 deg. pressure angle, stubbed to the following proportions:

Addendum 8/10 divided by the D.P.

Dedendum, 1 divided by the D.P.

Pitch diameter equals number of teeth divided by the diametral pitch.

BROWN & SHARPE No. 13 HEAVY AUTOMATIC GEAR CUTTING MACHINE

For Spur and Bevel Gears

Particularly well suited to the rapid roughing out of large bevel gears, this machine is also used for finishing bevel gears where speed of production is of primary importance. Spur gears can be roughed out and accurately finished on this adaptable machine, a feature which should appeal to manufacturers and users of large machinery with sizeable repair shops. Investigate the production possibilities of this machine.

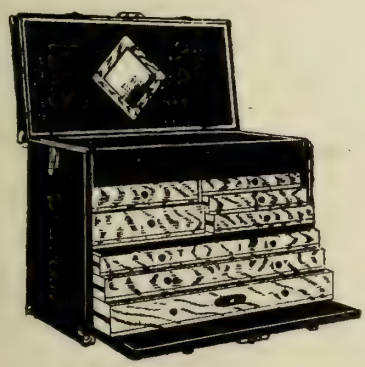
GARLOCK MACHINERY LIMITED

WOOD WORKING AND METAL WORKING MACHINERY

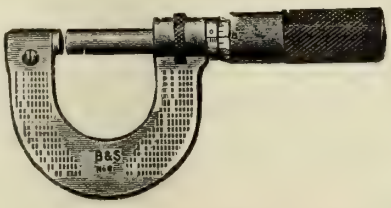
163 DUFFERIN ST. TORONTO **TELEPHONE, PARKDALE 7855**

SPECIALISTS IN METAL-WORKING AND WOOD-WORKING MACHINERY

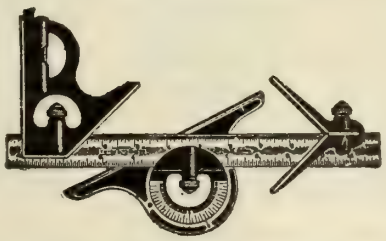


An up-to-date mechanic always takes pride in keeping his tools in first-class shape. Why not purchase a good TOOL BOX from US and keep your tools correctly?

We have a very large assortment of these boxes at reasonable prices, and will be pleased to show you the complete range. They are strong, durable, and attractive in appearance.



We carry a wide range of micrometers, and only the best lines. We believe the good mechanic will demand the best obtainable, therefore we carry only the lines which have an established reputation.



Here is a combination which is exceptionally useful and yet very low in price considering the quality and versatility of the articles shown. Enquire for this combination square, angle and protractor set.

TOOLS OF ALL KINDS

We can supply you with tools for the mechanical, building, electrical and all other trades. We carry a well-assorted stock, and when in need of tools of any nature write us your requirements and we will give you prices and all other particulars. Better still, drop in and see us. We will make you welcome.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

New pressed steel end construction, in place of heavy cast steel ends, makes the crane considerably lighter without sacrificing strength. This feature plus large wheels with flexible roller bearings makes the Curtis still easier to start, easier rolling and longer lasting. They are simple to erect, unusually rigid and safe. Made either single or double I beam type suitable for use with air hoist, chain block or electric hoist. Write for full particulars.

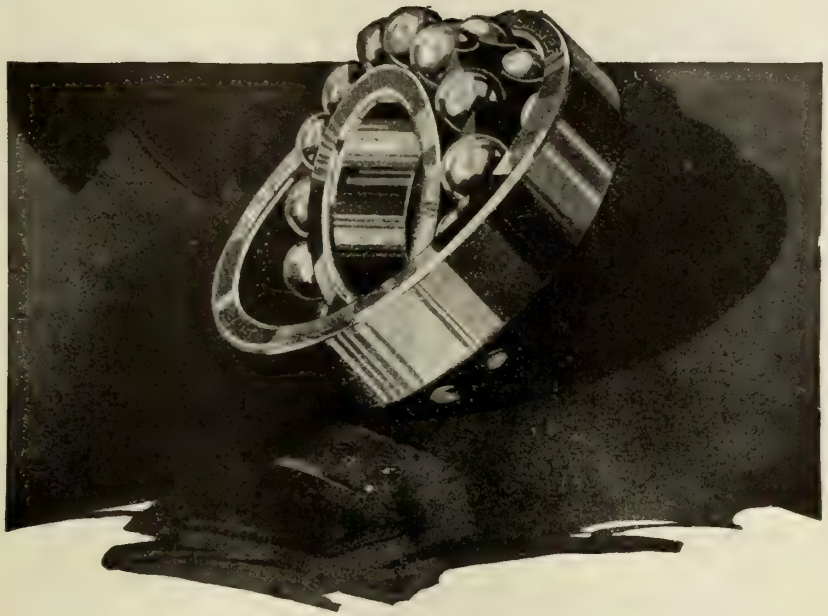
SKF



Wherever Misalignment is a Factor

THE operation of your machine will not be successful unless its bearings function in complete harmony with other parts. Deflections in the shaft, weaving in the frame and other causes may create severe stresses in all parts of the bearing, unless the latter has some inherent means to compensate for this misalignment.

The SKF marked self-aligning bearing operates on the same principle as the ball and socket joint and is therefore capable of taking care of the severest misalignment. Moreover the aligning action is positive, immediate and automatic.

The self-aligning bearing is a product of the Canadian SKF Company, Limited, and is sponsored by the SKF Industries. Its manufacture embodies all the minute care, precision and quality for which the mark SKF stands. The world-wide experience of this organization is put at your disposal, free of any obligation on your part.

Watch the Teeth of Your Files

As soon as the teeth of a file have lost their original keenness, the file should be discarded.

Otherwise, time and effort are wasted. A new file costs less than that unproductive labor costs.

These standard brands retain their keenness for the maximum time.

Cut Your Painting Costs The "SPRACO" Way

It makes some difference!--

whether you paint 1,000 sq. ft. a day or 8,000 sq. ft. a day. Yet that's the difference in the cost of painting buildings, bridges and other large structures by hand and brush and of painting it with the Spraco Paint Gun—for the same amount of time and labor are consumed in each case.

"SPRACO" Pneumatic Painting Equipment

effects tremendous savings. One handy man with Spraco Pneumatic Painting Equipment can outstrip five or six men with brush and pail. And he will use less paint, lay on a smoother, more uniform coating and get into cracks, crevices and corners where good hand-brush work is impossible. Thus saving 70% in labor and time while doing much better work.

It is not unusual for a good workman to cover 10,000 sq. ft. a day on factory interiors with the Spray Gun—and do a thorough job.

There are Spraco painting devices for every class of work from the finishing of the finest furniture to the painting of the hulls of ships.

Why not investigate to-day?
Send for "Spraco" Bulletin No. P-73.

What Kind of Securities In Your Strong Box?

Is every bond you hold paying interest regularly and are all your stocks earning dividends? Are your life insurance policies the best for your needs? Are your investments the kind that will help you attain your ambitions?

You ask yourself these questions from time to time. If you feel the need of advice in investment and financial matters, if you want to keep informed as to business movements affecting yourself you need THE FINANCIAL POST, Canada's dominant investment weekly. $5 will bring it for one year, 52 issues containing the solution of your own investment problems.

Pin $5 to this advertisement (or your letter), write your name and address and mail to us to-day.

THE FINANCIAL POST
143 University Avenue, Toronto

What do you look for —in a Spring?

DO YOU look for quality—so high that the spring will function efficiently under all conditions; that it will "stand up" under the severest usage; that it will outlive several others in usefulness?

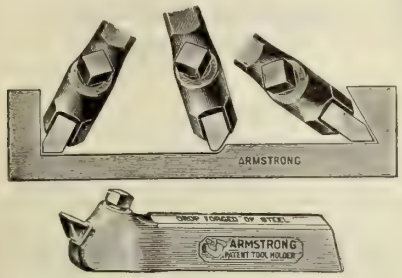
These are attributes long associated with RAYMOND SPRINGS and which owe their being to scientific heat treatment by experts and the facilities of our up-to-date plant.

There is a RAYMOND SPRING for every purpose.

Raymond Mfg. Co., Ltd.
Corry, Pa., U.S.A.

Tool Holders vs. Forged Tools

One Pound of Steel



Equal to 10 Forged Tools

THE simplicity, strength and convenience of Armstrong Tool Holders is appreciated by practical machinists. They recognize the fact that the saving in time, steel and annoyance effected by Armstrong Tool Holders can hardly be over-estimated.

Where they once carried large stocks of heavy tool steel and ground it to waste, they now turn up cutters from the bar at less than one-tenth the cost. Send for catalogue

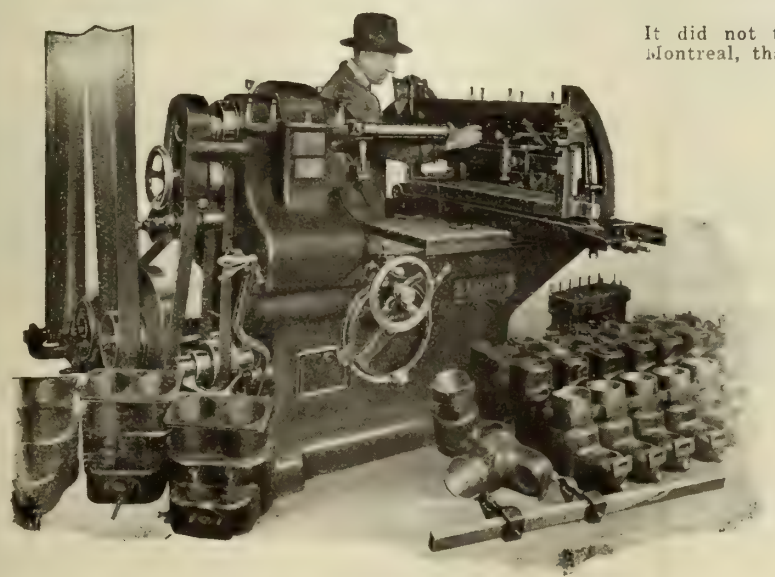
Why Not Increase Your Profits Too?



No. 5 Cylinder Grinding Machine in the plant of H. E. Bourassa, Montreal.

It did not take long to convince Mr. H. E. Bourassa, of Montreal, that this

LANDIS No. 5 CYLINDER GRINDING MACHINE

is a money-maker for Garages, Repair Shops and small Machine Shops—it increased his profits right from the start.

The Landis No. 5 Cylinder Grinding Machine assures big returns from your investment. It was specially designed for rapidly and accurately regrinding motor vehicle cylinders.

Set-ups are easy and operating time is speedy. In addition, it has a range as broad as the **Landis** reputation in the machine tool field and will handle any type of cylinder that comes into your shop.

Send for "Interesting Facts on Regrinding"—it's free on request.

THE UNITED STATES ELECTRICAL TOOL CO.
CINCINNATI, OHIO

To Holders of Five-Year $5\frac{1}{2}$ per cent. Canada's Victory Bonds

Issued in 1917 and Maturing 1st December, 1922

CONVERSION PROPOSALS

THE MINISTER OF FINANCE offers to holders of these bonds who desire to continue their investment in Dominion of Canada securities the privilege of exchanging the maturing bonds for new bonds bearing 5½ per cent. interest, payable half yearly, of either of the following classes:—

(a) Five year bonds, dated 1st November, 1922, to mature 1st November, 1927.

(b) Ten year bonds, dated 1st November, 1922, to mature 1st November, 1932.

While the maturing bonds will carry interest to 1st December, 1922, the new bonds will commence to earn interest from 1st November, 1922, GIVING A BONUS OF A FULL MONTH'S INTEREST TO THOSE AVAILING THEMSELVES OF THE CONVERSION PRIVILEGE.

This offer is made to holders of the maturing bonds and is not open to other investors. The bonds to be issued under this proposal will be substantially of the same character as those which are maturing, except that the exemption from taxation does not apply to the new issue.

Dated at Ottawa, 8th August, 1922.

Holders of the maturing bonds who wish to avail themselves of this conversion privilege should take their bonds AS EARLY AS POSSIBLE, BUT NOT LATER THAN SEPTEMBER 30th, to a Branch of any Chartered Bank in Canada and receive in exchange an official receipt for the bonds surrendered, containing an undertaking to deliver the corresponding bonds of the new issue.

Holders of maturing fully registered bonds, interest payable by cheque from Ottawa, will receive their December 1 interest cheque as usual. Holders of coupon bonds will detach and retain the last unmatured coupon before surrendering the bond itself for conversion purposes.

The surrendered bonds will be forwarded by banks to the Minister of Finance at Ottawa, where they will be exchanged for bonds of the new issue, in fully registered, or coupon registered or coupon bearer form carrying interest payable 1st May and 1st November of each year of the duration of the loan, the first interest payment accruing and payable 1st May, 1923. Bonds of the new issue will be sent to the banks for delivery immediately after the receipt of the surrendered bonds.

The bonds of the maturing issue which are not converted under this proposal will be paid off in cash on the 1st December, 1922.

W. S. FIELDING,
Minister of Finance.

Keep Production At Top Speed

Efficient production demands elimination of lost time. By making your gasoline supply easily accessible, at every needed point, Bowser Piston-Type Measuring Pumps save workmen's steps and time.

The long-distance pump delivers gasoline where it is to be used and measures it in the exact amount required, without spillage or waste.

The patented Bowser centrifugal separator assures clean, power-full gasoline, free from all moisture and sediment. The double cog rack assures easy operation.

Bowser equipment provides large underground facilities, enabling you to buy gasoline at quantity prices, eliminating the fire hazard and assuring minimum insurance rates.

To save money and speed up production, write for illustrated Booklet C-13.

Doing It Pneumatically

IT SOUNDS as though Dean Inge, the man of gloom, might have said it—that the pneumatic hammer is, of all tools, most typical of modern life, with its speed, its noise, and its generally nervous disposition. But to be fair to the hammer, even if it does detract from human merit, the tool is noted for its efficiency. Herein the comparison may lose its adroitness for air, hot or cold, is not commonly associated with persons who have gained appreciable reputations.

PNEUMATIC hammers represent a small part in the development of utilities to which compressed air has been applied. It is but one of a great variety of functions, although its voice is the voice of industry. Where drilling, ramming, hammering, riveting, caulking and boring are to be done, compressed air is employed. Hoists, jacks, cutters, grinders, bull-dozers, presses, paint sprayers, and sand blast attest the high efficiency and economy of air.

Old chronicles are interesting, and they reveal that in 1667 some genius "described a plan by which the air in a tube was exhausted in such a way that a piston working in the tube would be drawn in the direction of the suction." He had discovered the pneumatic despatch tube. This, however, was in the reign of Charles II, whose memory not only recalls Paradise Lost and Pilgrim's Progress and Puritanism, but also the founding in 1660 of the Royal Society for the Promotion of Natural Science. It brought together men who are said to have thought more about air pumps than about theology.

The first useful pneumatic tool was a rock drill, having a hammering piston, patented in England in 1865. This was also used in riveting. Followed in 1867, a drill with a grasping handle with controlling throttle valve. The first pneumatic hand tool is said to have been a dental mallet which appeared in 1897. Then came many American developments, including in 1899 a "long-stroke pneumatic hammer where a short piston travelled a distance greater than its own length." Such names as Keller, Tierney, Kimman, Richards and Meissner appear in the records of development of pneumatics and apparatus of the valve and valveless types soon displayed great variety of design to meet many requirements.

Pneumatics have lent themselves wonderfully to that phase of mechanical economics embodied in bringing the tool to the work. Ship-building, locomotive and rolling stock construction, mining, steel fabrication, the building of skyscrapers, owe much to pneumatics. They have contributed their part to sanitation and cleanliness, have eliminated many laborious operations in work of all kinds and have made speed and efficiency compatible terms in many fields of activity. The introduction of the air brake in 1869 revolutionized railroading, and much other safety apparatus is dependable upon compressed air. The railroad machine shop without pneumatic equipment would find its equivalent in a reversion to horse cars for city transportation service. While here it may be observed that the gigantic program now being carried out by the Transportation Commission in Toronto in tearing up miles of pavement and car tracks and laying anew, has been facilitated immeasurably by the most practical application of pneumatics—drills, hammers, tampers, etc. It was here that team work employing electricity and compressed air was seen to particular advantage.

Many are the utilities of compressed air and pneumatics. The term "do it pneumatically" carries with it great significance to the modern industrial world and to all engaged in it.

Air Tools—Manufacture, Service and Operation

Early Development of Pneumatic Equipment—Rapid Improvement in Design and Efficiency—Accuracy of Construction—Every Tool Carefully Inspected and Tested—Proper Oiling Necessary

THIS article has been prepared with the desire to create a personal interest in pneumatic tools by showing how carefully they are made, which it is hoped may eventually improve the conditions surrounding their care and use. The manufacturers of air tools owe a lasting debt of gratitude to the foundrymen of the past two decades for their generous assistance during their early struggles for recognition and for the opportunity afforded them of using the foundry for their experimental work.

The first model of the air tool was the reciprocating type of machine such as the riveting and chipping hammer in which the plunger is thrown back and forth in the hammer cylinder by compressed air, the action of the plunger being controlled by an air operated valve enclosed in a valve cage at the rear end of the hammer cylinder. The first tools were, of course, crude in their construction, very heavy and hard to hold on the work as no way at that time had been discovered to cushion the blow of the plunger on its return stroke, and it hit about as hard in one direction as in the other. Operators complained about the "kick" and the excessive vibration, and some trouble was had to induce men to use them at all. Notwithstanding these discouraging features the inventors did not lose faith in the ultimate success of the air hammer, but steadily pushed on, making changes here and there which eventually overcame the trouble.

Early Air Motor

Following closely on the heels of the riveting and chipping hammer came the air motor, likewise crude and heavy at the start. Several different types were tried out and finally the four-piston motor was found best for general work and was adopted as the standard type of air motor. As time progressed, so also did improvements of air tools, and the manufacture of them in large quantities began in earnest. Capital was attracted to this new industry and companies were formed and factories built for their production on a large scale.

It is not the intention to write an extended history of pneumatic tools, or follow them through every change of design which has occurred in the past 25 years, but merely to touch the high spots, giving a glimpse of the beginning of the industry as compared to present day construction. Air tools have now reached such a degree of perfection in design, workmanship and operation, that it seems impossible to further improve them. Every type of pneumatic tool now made is used in some capacity in foundry service, for which they were originally designed. Other steel industries finally adopted the air tool, but only after the foundries had been using them successfully for several years.

Pneumatic tools have revolutionized the world's work in the fabrication of steel, in the mining of coal, gold and silver, in the quarrying of rock, in monumental work, and in the foundry. They built the battle fleets of the world and every steel ship afloat. The air gun is the "peace gun" of the future, and will help rebuild the countries destroyed by the ravages of war.

Heat Treating Handles of Air Hammers

The handles are first heated uniformly to the desired degree of heat, depending upon the carbon ratio, then are cooled in oil, again re-heated for temperment in the drawing furnace and air cooled. The handle forgings after heat treatment are carefully polished and sand-blasted, which gives them a velvet-like finish.

When turning hammer cylinders from bar stock, the cutting tools have tubes through which the cutting compound is fed to the cutting edge of tools,—the bar holder used in reaming the cylinder bore has inner bearings through which the reamer operates, insuring perfect alignment and uniformity of the holes. The drill press is used to bore the long ports in hammer cylinders, each cylinder having six long ports, varying in length from 3 to 12 inches in depth and ⅛ to 7/32 inches in diameter. The internal drilling tool is ingeniously designed to operate

Figs. 1, 2, 3.—Caulking and chipping with air hammers.

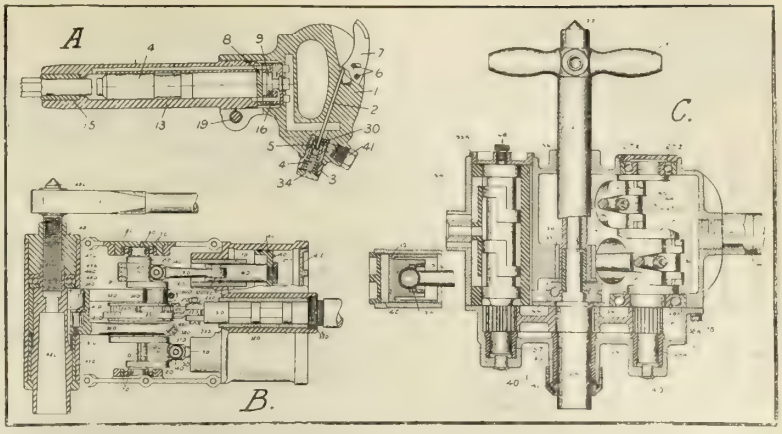
within the bore of the hammer cylinder and drills holes at right angles to meet the down holes in the wall of cylinder. The old practice of drilling from the outside of cylinder and plugging holes is now obsolete.

Tempering Room

In this room all tempering of steel parts is done, it is provided with every device for the proper hardening of the different parts of the air hammer and air motor. Some parts require different treatment than do others, based on the service and strain to which they are subjected. Some parts are made of mild steel and are given surface hardening only, which is better than hardening throughout; delicate pieces are heated in lead.

Inspection Room

Every necessary implement for measuring, gauging and testing for hardness is employed here, a triple checking system is used to detect individual errors. Careful inspection is exercised at every stage of manufacture, and all parts rigidly tested for extreme service so that any weakness which may have escaped surface inspection may be detected before final assembly. Both external and internal grinders are used in finishing hardened parts, such as plungers, valves, valve blocks, cylinders of chippers and riveters, motor valves and pistons, cranks and other hardened parts of air tools. Accurate jigs and templates are provided for each kind of part to insure extreme accuracy in their production. The finest machinery obtainable is used in the production of air tools, each machine is selected and properly tooled for the class of work upon which it is to be used.



Sectional views of hammer, corner drill and four-piston air drill.

The Assembling Room

The assembling of air hammers, air motors and other tools requires men of a high order of intelligence. The general knowledge they acquire in this department fits them for the saleswork to which they are promoted as occasion requires.

We have given but a bare outline of the construction of air tools, sufficient however to convince the reader that the most painstaking care is exercised in the making and finishing of each individual part entering into the complete air tool, thus insuring perfect interchangeability of all parts when required for replacements.

Care and Use of Pneumatic Tools

Compressed air is the most useful power generated; unlike steam it can be piped long distances without much loss in transmission if large pipes are used. Builders of air compressors have given some very reliable data on the transmission of air and the loss in pressure by friction. They claim a frictional loss of 8 lbs through a 1-inch pipe in a travel of 1,000 ft. but no appreciable loss in the same distance through a 3-inch pipe. It is unfortunate when reliable data may be had, that users of air should continue to use small pipes in their systems and numerous elbows, all of which are so detrimental to the efficient operation of air tools.

There are four indispensable things required in the successful operation of the air tool, and these are dry air, volume, uniform pressure and lubrication. Dry air may be had by piping the receiving tank in the following manner: The receiving tank should be of generous size even larger than the usual sizes specified for standard size compressors for the reason that the process of cooling and draining moisture from the air in the initial tank is now recognized by users as a safeguard against moisture in the shop lines. The tank should be set in a vertical position and provided with a drain cock at the outside and close to bottom of tank. The intake pipe from the compressor should enter the tank above the center. The supply pipe (shop main) should be placed within 10 inches to 12 inches from bottom; this leaves a water space of 10 inches at bottom which can be avoided at intervals as needed. By this plan of piping the tank the air is trapped—the hot air from the compressor enters at center of tank, rises to the top as does each pulsation, as the air cannot escape except through the shop pipe at bottom of tank it must necessarily remain until cool—as it cools and drains it moves downward until it finally reaches the mouth of the shop pipe and moves onward through the system in good working condition.

Volume and Pressure

To maintain adequate volume and uniform pressure the shop mains should be large as they are the trunk lines which carry the air to the most distant points of the system, the mains should have a gradual rise until when they reach the most distant point they are considerably higher than the receiving tank. All branch lines which cross the path of the

main trunk line, from which they draw their supply, should always pass above and take their air from the top of the main pipe. If there is any water still in the mains it is at the bottom working its way back to the supply tank.

Compressed air is saturated with oil from the compressor and is never quite eliminated at the receiving tank where the first cooling of the air takes place as previously mentioned. A considerable proportion of the oil therefore passes on through the shop mains and branches to the drop pipes at which point the hose line is attached, leading directly to the air tool. The oil has a detrimental effect on the rubber inner tube of the hose causing it to disintegrate, particles of which become detached and enter the air tool, where they lodge in the valves and air ports of the hammer, causing serious trouble. The manufacturers of air tool hose were forced to find a remedy to correct this trouble, and finally brought out a type of hose having a composition inner tube which neutralizes the action of the oil to a certain extent but does not wholly eliminate the trouble.

Inventive minds working on this problem have recently discovered a simple device which we believe to be a solution of the trouble. This is an oil and water separator that may be made in your own shop at a nominal cost. It consists of a 3 foot section of 5 inch iron pipe, capped at top and bottom and attached to the branch air pipe lines which feed the drop pipes and hose lines. The branch pipe enters the separator at the top through one side of the cap and runs down the inner side of the separator to a point 3 inches from the bottom, when the air is liberated, escaping into the cylinder and returning to the top of the cylinder through a series of perforated baffle plates, the oil clinging to the baffle plates.

The air leaves the separator at the top, entering the branch outlet pipe attached to the cap at the opposite side of the inlet. The air is thus freed from oil and such water as may still remain in the system. The separator is drained of its accumulated water and oil through the drain cock provided at the bottom of the separator. Occasionally the lower cap of the separator should be removed and the baffle plates cleaned by means of a stream of compressed air which quickly removes the oil adhering to them.

Fittings

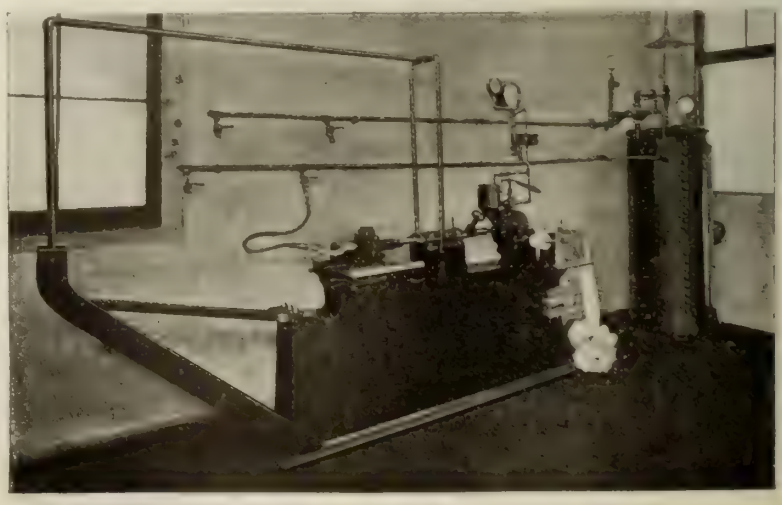
The selection of proper fittings that will offset least resistance to the passage of the air is just as important as large pipe lines to aid in the reduction of friction in transmission of the air from the drop lines through the hose to the air tool. Air valves which have any angle turns in the air passages are objectionable because they impede the direct travel of the air into the hose. Hose couplings, like the valve, should have an unobstructed air passage.

Lubrication

The close fit of all working parts of the air tool necessitates frequent lubrication, particularly in the riveting and chipping hammers. The oil used should be of good quality that will not gum, heavy black machine oil should never be used as there are numerous air ports in valve blocks and cylinders that must be kept open. The tendency of the heavy oil is to clog these parts, which impedes the proper circulation of the air.

If the air is charged with water it washes away all lubricant and the hammer loses its efficiency, refuses to work and the delicate parts and polished surfaces become rusted. The hammer should have a bath every night in coal oil, which soaks up the worn out oil of the day, and each morning should be attached to the hose and blown out thoroughly, then fresh oiled and put in service. If treated in this fashion it will perform like a new tool.

We do not deem it necessary to dwell further on the care and use of the air tool, except to recapitulate and say that if dry air, in sufficient volume at adequate pressure, be furnished, plus suitable lubrication, we predict that your air tool troubles will be greatly reduced and the working efficiency of the equipment correspondingly increased.



All hammers are tested on this machine before leaving the factory.

Utilization of Compressed Air on Draw Presses

Overcoming Difficulties of Wrinkled and Broken Pieces—Air Cushions Give Uniform Pressure on Drawing Ring—Heavier Draws on Lighter Presses—Used Singly or in Batteries

DRAWING operations on sheet metal frequently necessitate some intricate designs of dies and one of the vital factors involved in the problem is the character of the pressure that must be applied on the metal as the flat blank is drawn into the desired shape. This is a feature of sheet metal drawing that has always been difficult to overcome. The pressure on the draw surface should be just sufficient to keep the metal of the formed portion of the shell smooth at all stages of the operation. Should undue strain be placed on the metal at any period during the process, it destroys the toughness, often resulting in the cracking or splitting of the metal, either in that particular draw or succeeding operations. If the pressure is too light the result is to create wrinkles, and once these appear any attempt to reclaim the piece means failure.

The trouble is the irregularity of the pressure throughout the period of the draw, the use of springs or rubber giving an increasing resistance as the punch descends. The draw surface decreases as the piece is being shaped and extreme pressure on the smaller area causes excessive wear on the faces of the blank holders. In some cases the pressure of wrinkles, if not pronounced, is not objectionable but it indicates a poorly working set of tools. If dies are permitted to operate long under such conditions the rapid wear soon necessitates their removal to the tool room for repairs. It is always advisable to obtain as smooth a draw as possible.

Developments of Die Cushions

The double-action or toggle type of press was designed to produce a uniform pressure on the blank during the operation, and has proved a success in most cases. In some instances, however, this type of press has proved inefficient and pneumatic die cushions have been developed to remedy conditions. By means of these cushions a uniform pressure can be applied on the shell at all times regardless of the unevenness of the blank or the thickness of the metal during the operation. This is the greatest factor in favor of air cushions for this purpose, but there are others, some of which are as follows: (1) The initial cost of a single-action press equipped with pneumatic cushions which will perform operations usually performed on double-action presses, is only about one-half that of a double-action press. (2) The equipment is less cumbersome and can be operated at higher speed. (3) A machine provided with this equipment can be used for more than one purpose, whereas an ordinary drawing press is suitable only for a drawing operation. (4) A smaller machine can be used when air cushions are applied to supply pressure on the blanks, because it is not necessary to overcome increasing pressure, and so power is saved and unnecessary strain on the machine is eliminated.

Air Cushions of Various Types

In many instances air cushions have proved a successful and economical solution to metal-drawing problems.

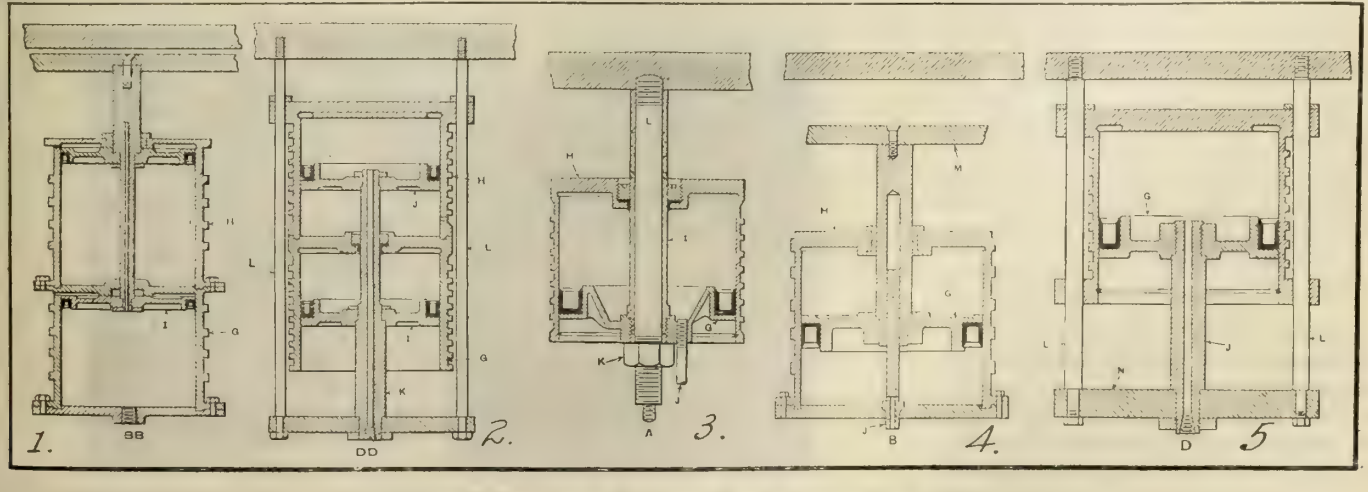
Various designs of these pneumatic cushions have been recently developed by the Marquette Tool & Mfg. Co., of Chicago. These are constructed to meet a wide range of requirements with pistons from 6 in. in dia., which are suitable for machines drawing shells to a depth of 2 inches, to cushions which have a piston 20 inches in diameter, which are intended for presses drawing shells to a depth of 8 inches. These cushions can be applied to machines singly or in batteries.

Design For Any Purpose

Some of these cushions are shown in Figs. 1 to 5. Fig. 1 represents a two-piston type of cushion. This design permits of double the pressure on the draw ring to that contained in the pipe line and tank. When there is sufficient room under the press it is usually an advantage to use this type when considerable pressure is required on the draw ring. Where large area blanks are being operated on cushions of this class are applied in batteries and as all are connected to a common source of supply, the pressure is uniform on all points of the pressure plate, a feature that eliminates the difficulty of adjusting springs under the pressure plate to the same tension. These are particularly applicable to the drawing of auto body parts, steel barrels, radiator fronts, fenders and similar large pressed steel parts. It will be noted that in this type the pistons are attached to the pressure plate, while in that in Fig. 2 the cylinder is the movable member.

Stationary Piston Type

In Fig. 3 the piston G remains stationary when air is admitted into cylinder H, while the cylinder rises vertically on sleeve I. The pins that support the drawing ring of the die rest upon the top surface of the cylinder, and thus as the cylinder is forced upward, pressure is applied on the drawing ring. The air is admitted into the cylinder through pipe J. Nut K permits the various parts of the cushion to be removed from the machine without requiring stud L to be disassembled. This cushion design is used singly, as a rule, but it can also be applied in mul-



Figs. 1 to 5.—Sectional views of various types of pneumatic die cushions.

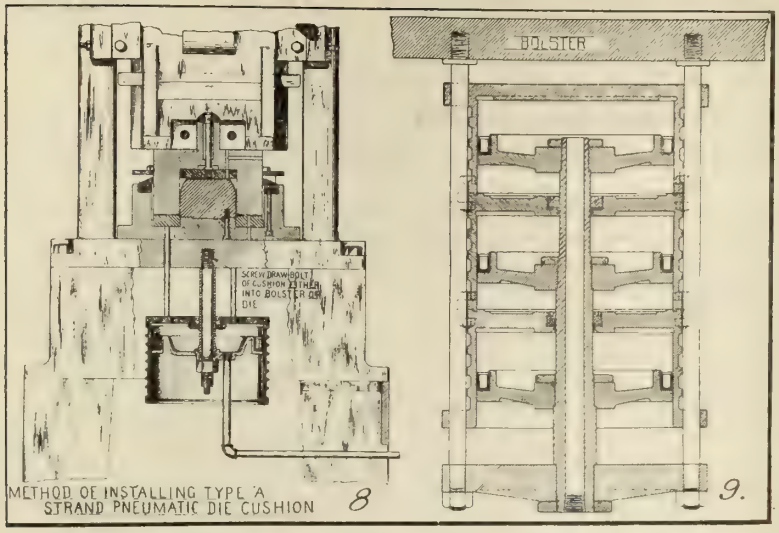


Fig. 8—Method of installing die cushion.

Fig. 9—Three-piston type of cushion.

tiples on double or multiple-crank presses.

Movable Piston

In the design shown in Fig. 4, cylinder H remains stationary and piston G is forced vertically upward when compressed air is admitted into the cylinder through connection J. The drawing-ring pins rest upon the pressure-pad M. This type of cushion is installed principally in batteries on double or multiple-crank presses. Another design of cushion in which the piston remains stationary while the cylinder is forced upward when air is admitted into it is shown in Fig. 5. Piston G is supported upon fitting J through which air is forced into the cylinder. This fitting is mounted in plate N, which is attached to the bolster of the press by four rods L which also act as guides for the cylinder. The die pins rest upon the top of the cylinder.

The battery method of installation should be used when a number of presses are connected to the same main tank of compressed air. It is very important to provide each machine with an individual supply tank and an air regulator so that a definite pressure can be maintained on any one machine independently of the rest. When only one machine is supplied from the main tank the cushion can be connected directly to it. It is advisable to keep a record of the pressure on each job so that experiments are unnecessary when a similar operation has to be performed. The total pressure on the draw ring can be determined by multiplying the pressure in pounds per sq. in. by the area of the piston in square inches.

Uniform Pressure

In order to exert an even pressure on the drawing ring during an entire operation, it is necessary that the individual tank used in conjunction with the cushion be of ample capacity. When the tank is too small, the air pressure will be greatly increased as the air in the cushion is forced back into the tank on the downward stroke of the press ram, and, of course, the pressure on the drawing ring will be subsequently greatly increased. If the tank is large enough, however, no trouble arises from this source. The air cushion should also be of sufficient size so that a high air pressure in pounds per square inch is not necessary in order to obtain sufficient pressure on the drawing ring. One-stage air compressors are generally used in connection with these cushions, but their operation is uneconomical when the air pressure is more than 100 pounds per square inch. Besides this, excessive pressures are detrimental to the cushions. More pressure is required on the drawing ring when a part drawn from a thin-gauge metal is being produced than when a thick-gauge metal is being used, and so it is evident that a larger cushion is required for drawing light metal than for drawing heavy metal.

Making Steel Helmets

The production of steel helmets for the United States Army was a metal problem which occurred during the recent war. These helmets were drawn from a high manganese steel of about 0.036 inch in thickness. The specifications required that the minimum thickness of the helmet should not be less than 0.030 inch at any point and that the height from top of the crown to the rim should be 4⅛ inches. It was generally thought that two operations on double-action presses were required to produce the part, and this method was used with varied success.

Difficulty Solved

The above facts were called to the attention of the firm by a manufacturer who desired to produce helmets on a single-action press. The press was subsequently equipped with pneumatic die cushions, the female part of the die being held in the press ram. A pressure of about 21 tons was applied on the drawing ring by the cushions. The result was an average production of nine helmets per minute, the surfaces of which were smooth and the minimum thickness of each shell not less than 0.032 inch. The reason that the helmets were drawn in this manner without being excessively stretched was that the pressure on the drawing ring was the same during the entire operation regardless of the thickness of the metal. When these helmets were subjected to the shooting test, they were not penetrated by bullets, owing to the fact that the metal had not lost any of its toughness as a result of the drawing operation.

Several Installations

Fig. 6 illustrates a large draw press equipped with a battery of double-piston air cushions for drawing auto fenders of all types and dimensions. The press operates at a speed of 10 r. p. m. It has a long stroke and is fed continuously without stopping. Fig 7 shows a Niagara press equipped with a battery of single-cylinder pneumatic die cushions used for drawing automobile bodies, the die cushions replacing the pile of heavy coil springs shown at the side of the machine. Fig. 8 shows a sectional view of a die cushion installation. The draw bolt is screwed into the die or bolster. The necessary number of spacing collars are then placed on the draw bolt to keep the cushion at the proper distance from the die; the cushion is passed over the draw bolt and additional spacing collars placed on the draw bolt. The nut is then placed on and air connected. Fig. 9 illustrates a special, heavy draw air cushion fitted with three pistons.

Cleaning of Machine Parts by Sand Blasting

Widening Application of the Process—Installations to Meet a Variety of Needs—Mechanical Handling and Screening of Sand —Constant Change of Air Required—Automatic Equipment

HOW little does the average person realize to what extent the process of sand-blasting is utilized in every phase of life and industry. Your morning bath is taken in a cast-iron tub —sand-blasted to prepare it for enameling; the nickle-plated faucets through which the water is run are also subjected to the same treatment before they are plated in the plating bath. Your breakfast is probably cooked on an enameled range, the parts having been cleaned with a sand-blast to prepare them for the coating of enamel. After you step into your auto to go to business; the motor has been sand-blasted in one plant, the transmission gears in another, and if wire wheels, the metal in the felloes has been cleaned by this process before it is fabricated. On your arrival at the office you are probably carried to the upper floors in an elevator cage which also has been sand-blasted. As you reach for the telephone you do not stop to think that its parts have also been sand-blasted before fabrication. You may have stopped on your way down to get shaved. In that event you sat down in a barber's chair that had also been similarly treated before it had been enameled and nickeled. Possibly your tooth aches, and as you stop into the dentist's office his white furniture has also been sand-blasted for enameling, and it may be that the handles of his tools have been given a matte finish with the blast so they will not slip in his hands. At noon, at the hotel or club, the dishes on which your meal is served have been sand-blasted before receiving the glazed finish. In the afternoon you may attend a funeral. If a metal casket is used, this too has been cleaned by a blast of sand, and if the monument maker is at all progressive, the head-stone has been lettered with the sand-blast. Possibly at the end of the day you slip into an enameled bed, and reach to turn off the electric light, both of which have also been sand-blasted.

Varied Application

Sand-blast equipment is not necessarily designed to a single trade, as for instance the same machine that sand blasts dishes is also used for cleaning automobile crank-shafts and other metal pieces. As a rule the type of machine selected is governed more by its size to accommodate the pieces and its method of handling them, and the blast action is accommodated to different commodities by regulation of pressure and grade of abrasive.

Every foundry has conditions and operations peculiar to itself. A sand-blasting installation should be an entirely individual problem. If you are to get results, which is the final test of the cost of a sand-blast system, it is necessary to secure experienced advice from those who have made a special study of sand-blast engineering and practice.

Four General Groups

Basically sand-blast machines will divide into four general groups as follows: Hose machines; cabinets; barrels; and tables. The method of operation may be by either the direct pressure, the suction (syphon) or the gravity systems.

In direct pressure systems the sand is under pressure in a sealed container, sand and air being discharged in combination without expansion through a hose nozzle giving the greatest velocity and highest efficiency possible. The majority of hose machines are of the direct pressure type; indeed, the first application of sand-blasting was the hose machine type and it is still used without exception in sand-blast room installations. It offers a range of application that is possible with no other type. For a line and character of work that is varied and of medium volume it undoubtedly represents the most satisfactory equipment. Where the tonnage is large and the pieces are of a weight and size too great for convenient handling it is indispensable. The use of the hose machine demands some enclosure and experience has shown the wisdom and economy of a well ventilated and well lighted room for the purpose.

While the cleaning cost will always be reduced by mechanical methods of handling the work and the abrasive for reuse, a very convenient room can be provided with small outlay and may be built of rough lumber, with an exhaust fan in the ceiling or wall, carrying the dust-laden air into a settling box or chamber that will retain the heavier particles, the lighter material being carried off into the atmosphere.

Location of Sand-Blast

The inclusion of mechanical handling and screening of the abrasive makes a steel room most advantageous and economical. The simplest of these provides for the location of the sand-blast outside the room which is left free for the blasting operation, with controls extending inside to within easy reach of the operator. A mechanical separator, driven by a powerful air motor, at one operation removes both fine and coarse material. The clean, sharp abrasive for reuse is delivered by an elevator to a sand storage bin above the sand-blast machine for refilling. In this type of room the spent abrasive is shoveled from the floor to a chute in the side of the room connected to the separator.

Meeting Growing Requirements

As the daily tonnage rises, the capacity of the sand-blast installation expands (and without added cost for labor) in proportion as appliances are added for the mechanical handling of the abrasive, and the work is properly handled and routed. The problem of handling the abrasive can be met by a grated floor in the room through which the spent abrasive falls to a conveyor below, which carries it to the elevator boot. Built into the elevator system should be an efficient separating system, preferably a combination of mechanically operated screens, with an exhaust to remove the fine material. Thus both the coarse material that will not pass the nozzle and the disintegrated abrasive, core sand and all fine stuff without abrasive qualities are removed.

The clean, sharp abrasive passes to a storage bin and is afterwards refilled in

the machine and controlled from within the room. The waste material is carried to a bin with convenient outlets. An auxiliary sand-storage bin loads through a grating opening outside the room, and carries several days' supply of abrasive, which is fed to the system through a gate as renewal is required. This continuous operation may also be accomplished by placing the sand-blast machine itself in a pit beneath the grated floor, but the depth required for properly proportioned hopper to accommodate the entire floor area and the separating system results in a depth of pit and foundation that while showing no economy in cost even by the elimination of the conveyor and elevator, is frequently impracticable due to water conditions and also it makes impossible the advantage of the auxiliary sand-storage for handling the abrasive in volume. Where floor area is, however, at a premium this system may be found advantageous.

Light and Ventilation

Light and ventilation are of course necessary to adequately handle any considerable volume of work. Electric light fixtures with parabolic porcelain enameled reflectors will probably diffuse light equally to all points, and if fitted with protective fronts a perfect protection is afforded the lamps from flying abrasive.

Ventilation which should be ample will of course be governed by the requirements of the work in hand. No hard and fast rule can be suggested for this, but a constant change of air is required and this should be a minimum of say four to six changes per minute for the general run of brass and malleable castings, six to eight changes for cast iron and 10 for steel. A slow-speed exhauster of low horsepower requirements is most satisfactory as well as most economical.

Exhaust System

Some diversity of opinion is expressed as to the most satisfactory system for removing dust-laden air. Theoretically it is desirable to keep the dust in transit below the operator's head, and this theory creates some adherents for the down-draft system whereby the dust-laden air is drawn downward through the grated floor. Failure in practice to keep the gratings clear, however, seriously retards circulation and experience has demonstrated that more positive results are obtained from an up-draft, where there can be no interruption to the draft, and generally better operating conditions secured. As the dust is created where the blasting operation takes place, well above the floor line, and with a general tendency to rise, the up-draft system removes it without change of direction.

In considering claims for conditions provided within sand-blast rooms common sense tells us the dust is there and no improvement is possible over its removal as fast as created. Not only is this rapidity of removal essential from the standpoint of hygiene and sanitation, but equally so to provide for clear vision for efficiency in cleaning. Obviously protection for the operator from the dust-laden air and the flying abrasive other than afforded by the exhaust system must be provided. The most satisfactory device is a dust-proof ventilated helmet. Air is introduced into the helmet from the compressed air line, to which the helmet is connected by a small flexible hose, weighed over pulleys to take up slack in any position and permit ease of movement to the operator.

Cleaning Fragile Pieces

There are classes of work that by reason of shape do not adapt them to barrel cleaning. This includes precision work or pieces that are so light and fragile as to not admit of this method of sand-blasting and are yet too small for individual cleaning to advantage with the hose machine in room installation. For this character of output the automatic revolving table sand-blast, Fig. 10, has found high favor. A grated-top table half exposed and half housed revolves at a slow speed. Within the housed portion a series of nozzles, fed from a direct high-pressure hose blast, are oscillated in adjustment with the varying peripheral speeds of the table so that all points are brought with equal duration within the path of the blast stream. The pieces to be cleaned are placed on the exposed portion of the table as it revolves; they are turned as required and removed when cleaned. A flexible sectional rubber curtain permits passage of

Efficient Lubrication of Air Compressors

Good Body Oil Required—Destructive Nature of Carbon Deposit —Affects the Proper Operation of Valves—Danger of Vapor Ignition—Cleaning Compressor and Piping System

SECOND only to the mechanical construction the efficiency of an air compressor depends on the systematic lubrication of the reciprocating and other movable parts which come in contact with the air being compressed. The purpose of lubrication is to reduce friction to the lowest possible degree and minimize the carbonization of the oil. The element of friction is probably the most serious as this is the primary reason for using the lubricant. The oil selected should have sufficient body to sustain the weight of the moving parts and form a film that will effectually prevent the piston rings coming in direct contact with the walls of the cylinder. On the other hand the oil should not be so heavy that excessive power is required to overcome the viscosity of the oil itself.

Carbon Deposit

The accumulation of carbon deposit resulting from the carbonization of the oil takes on a sticky condition when first attaching itself to the bearing surfaces but after a time becomes hard and flinty. This objectionable substance adheres to the cylinder passages, on the valves and in the pipe lines and air receiver. The inefficient operation of most compressors may be traced to the sticking or partial closing of the valves caused by the presence of this carbonized scale.

Other factors may be responsible for the accumulation of carbon deposit, but those generally found are:—the use of unsuitable oil, such as that used for steam engine cylinders, an oil that decomposes easily and quickly in the heat of the air cylinder; the use of too heavy an oil where the excessive viscosity prevents proper atomization, thus remaining too long in a liquid state on the hot walls of the cylinder and quickly forming into sticky deposits of carbon; too great a volume of oil, as too much good oil may have the same effect as a smaller quantity of heavier oil. The protection of the air intake is very important, as the entrance of dust, especially from coal, is detrimental to the proper operation of the compressor.

Fire Hazard

Apart from the objections just mentioned the presence of carbon deposit should be guarded against on account of the hazard that is associated with it. Particles of carbon may be torn loose and becoming incandescent might come in contact with the vaporized oil, given off by the lubricant, and igniting, the resultant fire being great or small dependent on the amount of carbon and vapor in the piping and receiver. Danger from this source can be practically eliminated by systematic cleaning of the carbon deposit.

As the temperature of compressor cylinders is governed more or less by the pressure of the air therein, the consistency of the lubricant used should conform to heat requirements. At the final stage of compression the air that has entered at atmospheric temperature has been raised from two to ten times; for instance, when maintaining a pressure of 10 lbs. gauge the compressed air when on the point of discharge from the cylinder will have a temperature of 145 deg. F., while the final temperature at 250 lbs. gauge pressure will be about 750 deg. F.

Rise in Temperature

The following table gives the temperature in degrees F. for air compressed to pressures of from 10 to 250 lbs. per sq. in. These temperatures are for single stage compressors—when using two-stage units the final temperatures will be approximately half of that recorded for single stage.

Air Compressed to	Final Temperature
10 lbs. gauge	145 deg. F.
20 lbs. gauge	207 deg. F.
30 lbs. gauge	255 deg. F.
40 lbs. gauge	302 deg. F.
50 lbs. gauge	339 deg. F.
60 lbs. gauge	375 deg. F.
70 lbs. gauge	405 deg. F.
80 lbs. gauge	432 deg. F.
90 lbs. gauge	459 deg. F.
100 lbs. gauge	485 deg. F.
110 lbs. gauge	507 deg. F.
120 lbs. gauge	529 deg. F.
130 lbs. gauge	550 deg. F.
140 lbs. gauge	570 deg. F.
150 lbs. gauge	589 deg. F.
200 lbs. gauge	672 deg. F.
250 lbs. gauge	749 deg. F.

The above temperatures are not to be taken as absolute, as variations from those given in the table will occur when air cylinders are water-jacketed and from radiation. Under good working conditions the higher temperatures given may be less in practice, while heat may be greater when machines are working at high speed on light pressure. Given temperatures are especially useful in testing oils to determine their resistance against the formation of carbon when raised to high temperatures. These given temperatures, however, are not to be taken as limits establishing the highest allowable flash point for an oil that may be used safely in lubricating air cylinders.

Mineral Oil Best

The most suitable oil for the specific purpose of air cylinder lubrication would be a pure mineral oil of high quality, free from any animal or vegetable oil mixture. The oil should be carefully filtered. Oils that have an asphaltic base are to be preferred over those produced from a paraffin base, as no matter how carefully the oils may be filtered, a small portion of carbon content will remain. Carbon deposited from asphaltic base oils is of a fluffy nature and may easily be removed from the cylinder wall and valve seats, while that deposited from paraffin oils soon takes on a hard, flinty appearance and is difficult to remove.

When using paraffin base lubricant on medium pressure machines the physical test should conform to that given in the table below:—

Gravity, Baume ..... 25 to 30 deg. F.
Flash Point (open cup) 400 to 425 deg. F
Fire ..... 450 to 475 deg. F.
Viscosity (Saybolt) at 100 deg. F. ..... 230 to 315 sec.
Color ..... Reddish
Congealing Point ..... 30 deg. F.

Oil having the above test figures is generally recommended unless a compressor manufacturer specifies that a high flash point lubricant should be used to meet the conditions peculiar to that particular machine. The possibility of carbon deposit is more likely from high flash point oil.

Asphaltic-Base Oil

For the selection of a suitable asphaltic-base lubricating oil the table below has been compiled. The figures given are for average working conditions.

Gravity, Baume ..... 19.8—21 deg. F.
Flash Point (open cup) 315—335 deg. F
Fire ..... 370—400 deg. F.
Viscosity (Saybolt) at 100 deg. F. ..... 275—325 sec.
Color ..... Pale Yellow
Congealing Point ....—0 deg. F.

When compressors are first installed they require a greater volume of oil owing to the character of the friction surfaces, but after the walls of the cylinder become smooth the quantity of oil may be reduced to avoid the possibility of carbon deposit. No more oil should be used than can be absorbed for adequate lubrication. Too much may be as destructive as too little.

A leading authority on compressor engineering contributes the following: "The best way to determine the proper amount of lubrication is to take out the valves from time to time and examine the cylinder. All parts should feel that there is oil thereon. If they feel dry, the lubricators should be adjusted to feed a little more oil, whereas if oil lies in the cylinder and its parts show ex-

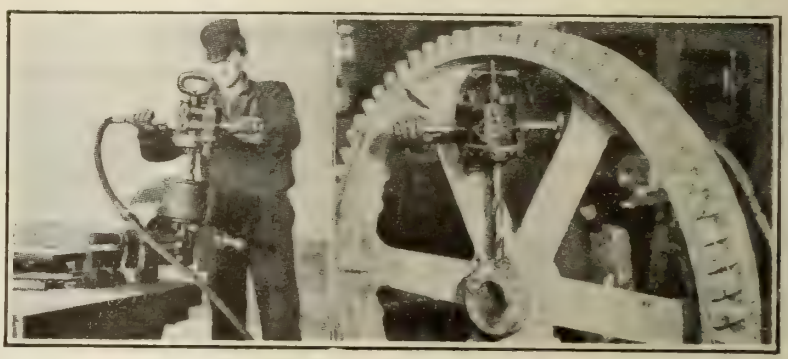
(Continued on Page 34)

Economy of Operation Dependent on Proper Care

Fine Mechanism of Air Tools Requires Special Attention—Keep Records of All Repairs—Place Responsible Man in Charge—Supply of Extra Parts Should be Stocked

WHEN you compare pneumatic tools with other shop equipment, such as the drill press, lathe and milling machine, you will observe that while the latter are of fine material and workmanship, the air tool is an exceptionally fine piece of mechanism. Being for portable use it must be sufficiently light for convenience in handling, while the service required demands great power and speed. Although other tools are generally used in the tool-room or factory under the most favorable conditions and kept well lubricated, cleaned and free from rust, the air tool is often used in the foundry or shop yard, exposed to sand or dirt and weather conditions and often goes without lubrication until it stops. However, in justice to the user we must say these conditions are fast improving, as he is beginning to realize the importance of caring for this equipment.

Probably the most important factor in any well organized system of maintenance of air operated portable equipment is that of proper facilities for adequate repair and storage when not in service. When a relatively large number of such tools are in constant use it is advisable to have a separate and distinct department especially equipped to look after all repairs. Every pneumatic tool in the shop and every length of hose should be kept track of by record, and a stock book kept to indicate any ordinary or special repair done to the machine, such as fitting new pistons, cylinders, etc. In any plant of considerable size there should be one man who is responsible for the maintenance of the hose and for keeping it in perfect order. In large plants it pays to have one or more inspectors doing nothing else but going round keeping receivers free from water and stopping leaks. He should be given power to put his knife through any faulty hose, and take the number of any man persisting in wasting air. Faulty hose will soon waste money enough to pay the wages of a good many men. Through imperfect supervision a drop of 15 lbs. per square inch has been observed in a plant of 5,000 cubic feet capacity, which was remedied in two days by a change of method of supervision.



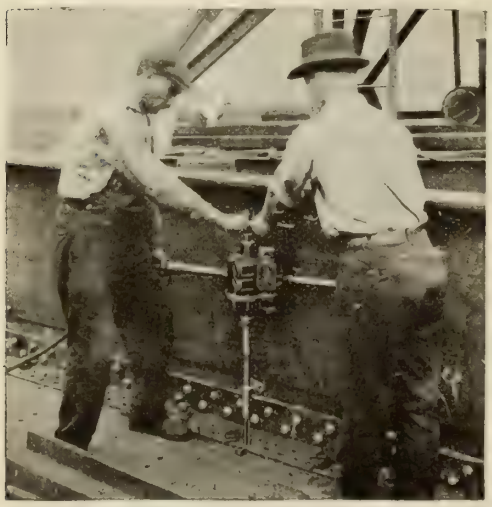
Left—Grinding throttle joints with reversible drill. Right—Piston air drill drilling 1-in. oil hole 3½ in. deep in cast steel gear wheel.

All hose used in connection with compressed air should be of the best quality fitted with a good oil-resisting lining. Poor lining deteriorates rapidly causing pieces to be torn away, stopping the passage of the air and entering and affecting the satisfactory operation of the motor. Very frequently, when a faulty machine is recorded, it will be found that the hose is the cause. Workmen should be furnished with a suitable check spanner, one that can easily be carried in the pocket, for tightening up the hose. It is advisable to supply him with extra washers for service in stopping leaky joints. Faulty connections and leaky cocks can easily be traced if the pressure is left on for a short time after work ceases, as the escaping air can readily be detected when other noises are stopped.

All the tools should be returned to the store at the end of the day, or sooner, if finished with. Tools left outside all night with moisture inside and out soon corrode and lose efficiency. This situation is not improved if the workman takes the next day off and the tool is still left lying about. A little firmness at the start, together with efficient checking of tool numbers, will convince the laziest of workmen that it does not pay to disregard this rule. But it must be clearly understood that the management should back up the tool room foreman strongly in this respect. Any weakness is fatal to the chance of success. Every tool should be looked over for injury or loose parts on its return to store. If anything is reported or noticed wrong, the tool should be passed straight to the fitter's bench, put right, oiled and then placed in its proper rack ready for reissue. Any tool likely to remain in rack for a lengthy period should be oiled and gently worked to allow oil to spread through the working parts before being placed in the rack. All tools should be placed in the paraffin bath at least once a week to clean them of grit. The sockets, etc., should be examined regularly to see that the gauge tools, i.e., drills, reamers, snaps and chisels fit accurately. This is important since in these days of high-speed steel a badly fitting taper socket means broken tangs on expensive drills and reamers; and sleeves worn large in hammers means loss of pressure and hitting power.

Generally speaking, beyond the replacing of worn and broken parts with

Cuts supplied through courtesy of the Independent Pneumatic Tool Co., Chicago.



Operating on bridge construction.

Lifting heavy roll with air hoist.

Working in close quarters.

those usually carried in stock in the tool room, very little can be done by the purchaser in the way of repairs to pneumatic tools. For instance, repairs to damaged drill casings, hammer cylinders and handles would be found rather difficult in the ordinary tool room. However, practical economy can be effected by a careful foreman in noting actual wear and tear, and keeping a good supply of spares for the parts that wear most. This may obviate a lot of trouble through tools being out of action, perhaps when most urgently wanted on a rush job. A good investment for the tool room is the provision of a portable testing outfit, consisting of a pressure gauge and air

Reaming end sills on steel car.

meter, capable of recording the air used by any tool in actual work. This is useful when buying new tools to test one make against another, and also to note the efficiency of any tool after so many months or years of use.

If the following rules are observed it cannot help but result in more efficient service and longer life for the air tool: Always blow out the hose and see that tool is well oiled before attaching hose. It will pay to use a lubricant of good quality. For drills use a good grease for crank chamber, and a light mineral oil—that will not gum—for the drill

Driving ¾ in. and ⅞ in. rivets on steel underframes.

valves and air hammers. Wash machines out occasionally with kerosene, after which they should be thoroughly oiled.

Oil tools at least once every hour when in service. Some plants adopt the system of having a man whose special duty it is to make the rounds of the shop, oiling all tools in service. By oiling around the chisel shank in chipping and calking hammers, the tool will work better and last longer.

Do not overload tools by selecting a machine to do work beyond its rated capacity. Care should be taken to see that air drills are the proper speed for the work. Do not use a high speed machine where slow speed is required. What is gained in speed will be lost in power and it will damage the motor.

When tools are taken out of service they should be returned to the tool room and placed in a solution of gasoline and signal oil, equal parts. This will cut the dirt or other foreign matter—then blow out thoroughly and lubricate before using.

Compressed Air in Saw Mills

FIRE hazard is an ever present problem in the operation of saw mills, particularly those of the larger variety where considerable haulage of material is necessary in transporting the timber and finished material to and from the mill. The danger that is associated with the use of steam or electric locomotives makes this class of equipment very unreliable from the factor of safety, owing to the possibility of sparks igniting shavings and inflammable material that abounds in industries of this kind. Compressed air haulage has many advantages over other methods where immunity from fire risk is of prime importance.

The efficiency of a modern compressed air haulage system, when properly designed is extremely high, comparing favorably with steam and electric haulage, over which it has the additional advantages of cleanliness and freedom from breakdowns; absolute elimination of fire risk; great flexibility of the system as a whole, since the locomotives are self contained all that is necessary to extend the system being to lay new tracks; and the fact that the air compressor, whether steam or electric driven is located in the power house under the eye of the engineer and under conditions most favorable to efficient operation. The system is so simple that anyone can handle it and if repairs are necessary, they can be made by an ordinary mechanic.

In lumber yards, where fuel is cheap and operating economy is not of first importance, the chief advantage to be derived from compresssed air haulage can be considered as the immunity from fire risk. This results in a material reduction in insurance rates, an advantage of the utmost importance.

Compressed air locomotives of the most modern two-stage design are very simple in construction and easy to understand, they are cleanly, have a large reserve power and a radius of action, in the various sizes, amply large enough, they are quicker and more convenient to handle than steam locomotives, they require no fireman and carry no coal or water. In operating economy they are far superior to storage battery locomotives and about equal to steam locomotives or electric locomotives taking their current from a trolley. The operating economy, compared to other types, cannot be accurately estimated since it depends almost entirely upon the type of locomotive and air compressor installed and upon the character of the installation in general. The question of fire risk and convenience far outweigh any slight difference in operation economy.

Many mills are now using air for the operation of drag saws, cut-off saws, log dogs, kickers, for putting the strain on upper band mill wheels, and many other similar devices. The pneumatic system has proven quicker, cleaner, more easily controlled and especially effective for fire prevention. It has the advantage that the power can be piped in from an isolated generating plant located at a safe distance from all inflammable material.

The installation of a dry pipe sprinkler system in saw mills is another recommendation for compressed air.

Pneumatic hoists for lifting, hauling and placing timbers, transporting and unloading cars, are a great convenience in any wood-working mill. The amount of air used is very small when compared to the added efficiency, the increased production per man and machine. Direct acting cylinder hoists are generally used for straight lifting work through limited distances, for keeping machines supplied with material, erecting machinery and other varied purposes. Air-operated tools of all kinds are extensively used in every up-to-date saw mill and wood-working establishment.

The air lift pump is another application where pneumatics has solved a problem of deep well water supply, a condition frequently prevailing in lumbering camps and large saw mills. The air lift pump is without question the simplest form of pumping apparatus made; there are no moving parts in the well, simply two pipes, an air and a water pipe. The operating compressor can be situated any distance from the well and any number of wells can be pumped by one compressor. The compressor is located in the power house, under the best operating conditions and under the constant supervision of the attendant. Two great advantages of the air lift pump are its ability to pump all the water a given size well will yield and the fact that, when there is sufficient water flowing to the well, the yield is increased with time.

Spray Painting and Finishing by Compressed Air

Spraying Method Maintains Quality and Reduces Production Costs—Suitable Booth Should be Provided—Agitation of Heavy Materials—Less Scaffolding Required on High Structures

By RAY W. TRIPP

WE ARE living in a period where the mechanical method is supreme, and shop worn, laborious hand processes are replaced by the more efficient and modern ones. The modern method of applying paints and finishing materials is of course, by means of compressed air and a spray gun. This practice although quite limited a few years ago has now become widely extended.

Competition to-day is exceptionally keen and for this reason alone everyone is compelled to reduce production costs. All devices which are designed to maintain quality and lessen labor outlay are receiving serious thought from the factory executive. Cost cutting methods have been found necessary in various shop departments, and the painting or finishing department has been no exception. The spray method of coating metal or wood products has solved the finishing room problem, as costs are cut, production increased, finishes improved, space is saved and the department is placed on an efficient and more healthful basis. Hand brushes are practically done away with, in fact, many of the newer factories have never used anything but a spray gun or air brush as they are sometimes called.

A spray finishing plant consists of an air compressing unit, a spray booth and the spray equipment with accessories, size of each depending on class and nature of work. The compression unit consists of an air compressor of sufficient size to furnish the required number of cubic feet of free air per minute at the proper pressure, an air receiver and motive power. The finishing is done within a metal spray booth equipped with a motor driven exhaust fan. The spray unit consists of material container, hose, spray guns, air regulating and purifying means and duster.

Observation and experience on many thousands of satisfactory installations have disclosed interesting facts worth noting at this time. When single coat work is wanted, a lighter or heavier coating can be obtained than is possible with a hand brush. Brush marks, skimped places and laps are entirely eliminated and the covering and wearing qualities of materials are increased. It is practical to spray fillers, shellacs, varnishes, enamels, lacquers or paints and materials giving good results when brushed will give equally satisfactory service when sprayed. Furthermore, the only practical way to apply lacquer to wood or metal is by means of the spray method. Inaccessible as well as irregular surfaces that are difficult to reach with a hand brush are rapidly coated with a spray gun. Any workman of ordinary intelligence can become a skilled spray gun operator in a remarkably short time. Price of hair brushes—a considerable item—eliminated. Time saved on sanding operation due to uniform surface produced by spray methods. Fire risk is reduced as all fumes and excess paint are exhausted. The two biggest points in favor of spray painting are the facts that one spray gun operator will cover as much surface as five painters using hand brushes, and will secure a more uniform coating which will be free of brush marks.

In order to obtain satisfactory results on some materials, such as cold-water paints, it is necessary to keep the liquid constantly agitated to keep the heavier parts in suspension. An agitating apparatus should be used when materials of this character are to be applied. The agitating is accomplished by means of compressed air, which, after passing through the attachment, bubbles up through the paint, and then escapes by means of the bleeder valve on the control head.

The average skilled hand-brush painter will apply from 2½ to 3 gallons of paint to about 900 or 1,100 sq. ft. of surface in an eight-hour day. An experienced operator with an efficient spray gun on such work as mill interiors can easily apply from 15 to 20 gallons to a surface approximately 7,000 sq. ft. in the same period of time. A speed of over 10,000 sq. ft. a day has been achieved in many instances. This is based on a covering capacity of about 350 sq. ft. to the gallon. On rough work, such as the hulls of vessels, special large size openings are used on the guns and speed of operation is greatly increased, with increased consumption of air and paint for surface covered. Speed up to 20,000 sq. ft. a day has been accomplished on this class of work.

One of the outstanding advantages of the spray gun when using the extension pole attachment is the saving effected in the erection of scaffolding, staging and long ladders. It is possible for the operator to reach eight feet or more from his standing position with as little effort

Author is associated with the Spray Engineering Co., of Boston, Mass.

Getting castings ready for shipment.

Spraying work that is hard to brush.

Putting the finish on interior wall.

as it takes a brush man to reach two. This is especially serviceable when painting large vertical or inclined surfaces, such as walls, ceilings, hulls of ships, stacks, etc.

When applying certain classes of varnishes and enamels it is often advisable to have the spray at a definite temperature somewhat higher than the surrounding atmosphere. For this purpose an electric heating attachment has been developed, which heats the air just as it enters the gun which assists in warming the material flowing through the gun passages. Where there is an excessive amount of moisture or oil in the air being used a separator should be installed in the pipe line to protect the spray gun from the possibility of clogging with dirt.

It might be well at this time to mention that resolutions favoring the use of spray painting machines were passed by the Paint Manufacturers Association of the United States and approved by the Board of Directors of the National Varnish Manufacturers Association.

Equipments are designed as a general rule for a special purpose, portable units for large work such as building interiors and exteriors, and stationary outfits for various classes of industrial finishing room work. In both classes there are small combinations where amount of work is limited, as well as larger where quantity production is needed. The selection of the right type of equipment and accessories is of greater importance than the average user appreciates and it would be advisable when in the market for equipment of this nature to place your problem up to a recognized manufacturer. With their years of experience in this line they are in a position to recommend the proper equipment and layout, and possibly make helpful suggestions as to the finishing of your product.

Compressed air has replaced manual labor and multiplied the efficiency of workmen in many lines, but especially in the application of protective as well as decorative surface coatings. The benefits to employer, employee and customer have earned a permanent place in modern business practice for spray painting equipment. It is without a doubt one of the most important agencies through which the wise and comprehending employer makes his employee's job a pleasant and healthful one, at the same time securing more and better work. Surely every user of paint or finishing material owes it to himself to fully investigate the possibilities of the spray method as applied to his particular work.

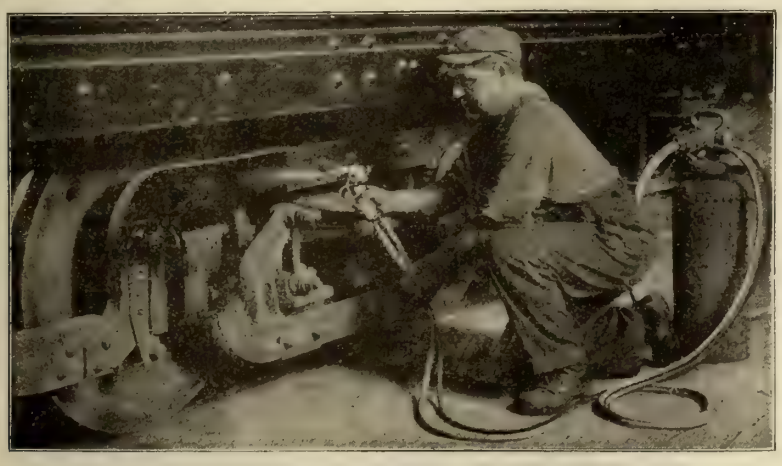
STEADILY INCREASING SERVICE FOR PAINT SPRAYING METHOD

Large industrial and manufacturing plants are now recognizing the economic advantages of painting by the spraying process. This is particularly true as regards the practice on railroads, as these companies have developed the method of painting to such a degree that the greater proportion of all equipment, including locomotives and box cars, are now painted in this way. One of the many advantages is that it is often possible to obtain equally good results from a lower priced operator than under the old brush method. The possibilities of economy may be appreciated by consideration of a typical example. A box car has been spray-painted by one 54-cent man in fifteen minutes, whereas it would take a 72-cent man about four hours to apply the paint with a brush. The relative amounts of paint used are nine and eleven gallons.

Finishing woodwork in offices.

BOOK REVIEW

Modern Workshop Practice is the title of a practical text book recently published by the D. Van Nostrand Co., New York City. The book is divided into 24 chapters, each one dealing with some phase of mechanical design, construction or operation. The opportunity has been taken by the author, Ernest Pull, to deal with some of the important improvements and developments made during the war. Included in the various chapters are those devoted to measuring tools and measuring machines; gauges and gauge systems; common workshop tools; soldering and brazing; bench work; heat treatment of metals; lathes; tool holders; lathe tools, speed and feeds; turning; screws and screw cutting; turret lathes; plain and universal milling; gears and gear cutting; gear hobbing and planing machines; boring and slotting machines; planing, shaping and drilling; grinding forge work; and power transmission. The book also includes 10 large folding plates, illustrating different views of large engineering plants. The book contains 675 pages and is profusely illustrated with half tones and line drawings. Price $5.00.



Showing a job that would be difficult to brush.

Showing application of extension pole attachment.

Relative Tendencies in Machinery and Pig Iron

Predicted Upswing in February and March Next Borne Out by Canadian Statistics—Graph Shows Change for Better is Due—Depression Since August Due to Labor Troubles—Demand Developed Strength

PREDICTIONS are made, based on records of iron and steel production and their industrial significance that demand for machine tools should show an upswing in February and March of next year. Authorities who have made the closest study of cycles, and have studied the indications and tendencies and comparisons of many years, declare that it has developed invariably that machinery business improves materially and has been known to assume its normal stride twenty months after pig iron production has passed its lowest point and moves toward higher levels. It is pointed out that the middle of 1921 saw the reverse peak in pig iron, and that this was a general characteristic of the business trend, or of the swing of the pendulum towards normal. It may be observed that August saw a still lower record, but according to procedure in calculations of this kind, the industrial unrest which caused this slump—or in fact any other trouble, such as wars—are but incidents in cycles which recur on an average of seven years. The present slump is one that affects one side of the problem, that of production. Demand has been good.

Official statistics based on Canadian industrial records show that movements in pig iron and in machinery have a relative significance. The accompanying chart illustrates the point. The upper line indicates pig production in Canada as between 1906 and 1922, a period of 16 years. The lower line is indicative of machinery demand, without specific relation to definite quantity or value, but as representing approximately the rise and fall in the years selected. The graph indicates at least that the peaks in the two industries have marked coincidence; that an uptrend in one is followed closely by a similar movement in the other, that the theory of seven-year frequency of depressions has some corroboration in the Canadian record, and that a decided change for the better is about due.

Pig iron production figures show an increase as between 1906 and 1907, during which period, it is a matter of record, machine tool business was good, while as to woodworking machinery demand, one manufacturer declares "We shall never see its like again." There was a sharp slump, 1907-08, and here, too, pig iron production declined. The improvement from 1909 up to 1913 was gradual but definite. The peak of pig production came in the latter year with 1,128,967 gross tons. Then in 1914, came a sharp fall to 783,164 tons gross, but with the war the turn for the better was greatly accelerated. Advancing prices are indicated by the fact that while in 1913 the tonnage above given was valued at $16,540,012, a tonnage of 1,090,396 in 1920 brought $30,319,024, the so-called composite price for the former being $14.65 per ton and for the latter $27.80 based on official figures of total production and value, although prices at certain periods during the war went to much higher levels. Following the armistice and cessation of munition making, there was again a drop in pig production, with an upswing in 1920, a year in which industry made good records. Last year saw a depression on which it is not necessary to recall harrowing details, while for eight months this year, due to strike troubles, the pig production has been little better than a quarter million tons. It will take some months for industry to assume its stability.

Following is the pig iron production record and values from 1906 to 1922, according to figures prepared by the Dominion Bureau of Statistics:—

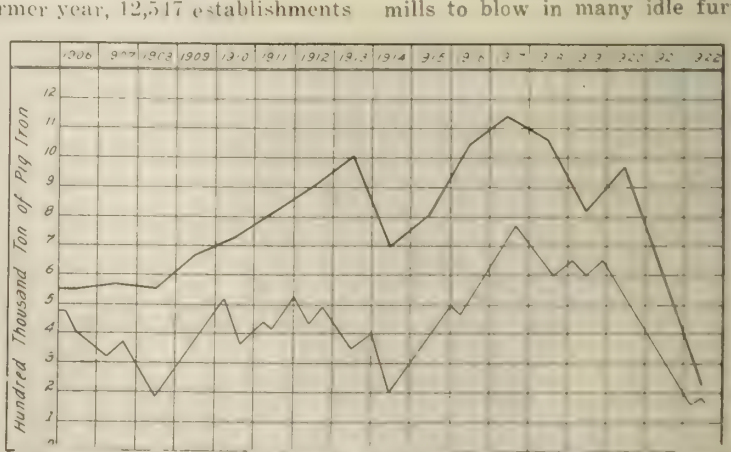
Annual production of pig iron in Canada
Years 1906 to 1922

Year	Pig Iron Quantity Gross tons	Pig Iron Value $
1906	598,411	$ 7,955,136
1907	651,962	9,125,226
1908	630,835	8,111,194
1909	757,162	9,581,864
1910	800,797	11,245,622
1911	917,535	12,307,125
1912	1,014,587	14,550,999
1913	1,128,967	16,540,012
1914	783,164	10,002,856
1915	913,775	11,374,199
1916	1,169,257	16,750,898
1917	1,170,480	25,025,960
1918	1,195,551	33,495,171
1919	917,781	24,577,589
1920	1,090,396	30,319,024
1921	665,676	
1922 eight months (See chart)	251,015	

Statistics show the remarkable industrial growth as between 1905 and 1918. In the former year, 12,517 establishments produced goods to the value of $706,446,278, while in 1918, the last year of the war, these had increased to 34,797, with products of $3,458,036,975. It was in those years of war that Canadian manufacturers established high standards of quality and production.

While the horizon may not appear at the moment as cloudless as all would desire, the stage nevertheless seems set for better things. The crop outlook, always a basic consideration, is most promising, demand for iron and steel continued good through midsummer and still shows strength, the unemployment problem has nothing of that acuteness apparent at this time last year, lumbering interests are preparing for heavy production in the woods this coming winter, the railways display some revival of buying interest, and all things considered, the prospect is full of promise.

Indicative of the trend affairs are taking in United States, a despatch from New York states: "The issuance recently of upwards of $80,000,000 of bonds, notes and other obligations was of especial significance in revealing to what extent the big industrial leaders of the nation are laying plans for business expansion. It is hardly likely that any such amount of money would be borrowed at this time unless the borrowers were able to see pretty plainly that they may derive extraordinary benefits therefrom. Newest reports from trade circles bear out this theory. In the steel industry especially steps are already being taken to revive the activity which was hampered materially by the shortage of fuel and the railway strike. Assurance that coal soon will be produced in an almost normal fashion and indications that a final settlement of the shopmen's strike is at hand have caused the steel mills to blow in many idle furnaces."



Comparison of movement in pig iron and demand for machinery since 1906. Upper line shows pig iron production, while lower line represents machinery fluctuations based on approximate estimate without reference to definite amount. Side figures refer to pig iron only.

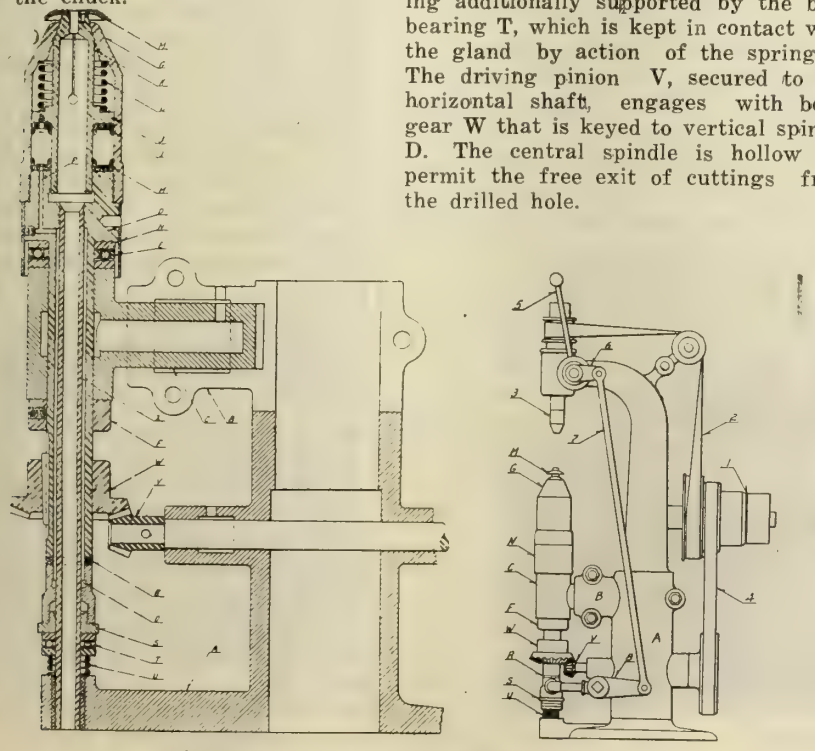
Practical Ideas From Practical Men

DRILLING CONCENTRIC HOLES IN SMALL ROUND PIECES

By R. Hamilton

In the manufacture of many small parts it is often necessary to drill a small hole in the centre of a piece already machined. When the part is of small dimensions it is often difficult to hold it conveniently and yet attain the required speed of production. The accompanying machine illustrates an interesting method of drilling a small hole in the short piece of ¼-inch stock and exactly in the center. The machine is so constructed that the drill spindle is made to revolve at a speed of about 1,200 r. p. m., while the lower portion that carries the work revolves at a speed of about 300 r. p. m. in the opposite direction, so that the actual speed of the drill in relation to the work is practically 1,500 r. p. m. This virtually insures a drilled hole central and concentric with the outer circumference. A notable feature in connection with the operation of this attachment is the joint control of the drilling and the chucking of the work with the one motion of the lever. After the work is placed loosely in the chuck the downward movement of the lever 5, which actuates the drill spindle 3, also operates the air valve on the lower end of the connecting rod 7, which is so adjusted that the initial movement of the sensitive lever opens the valve and allows air to enter the operating cylinder, the reverse motion of the lever raising the drill and releasing the chuck.

A detail sketch of the lower chucking arrangement and operating mechanism is shown in the sectional view. The frame or stand A is bolted to the bench, the upper extension B carrying the tee-piece C the vertical portion of which supports the entire mechanism. The outer spindle D to which the chuck is attached is supported on the ball bearing E that insures accurate movement with the least possible friction, vertical motion being prevented by means of the adjustable collar F. The shell G of the chuck is threaded to the upper section of the spindle D, the U-shaped leathers providing air tight joints between the outer cylinder and the smaller portion of the piston J, the top section of which is split to form the collet chuck K. When the air is released the collet is lowered by the reaction of the coil spring L. A small cup-shaped piece of sheet steel is fastened to the top of the collet to prevent the dirt or cuttings from entering into and destroying the sliding portion. A similar cylindrical shield is attached to the side of the main spindle to protect the ball thrust bearing E. The air enters by way of the inlet shown in the assembled sketch, and passes into the space O, up between the outer and inner spindles and through the small opening P, and thence into the cylinder. A fibre washer is used between the stationary connection and the main spindle to seal the air in its passage through the enclosed space. The lower portion is made air tight by the gland S; the spindle and gland being additionally supported by the ball-bearing T, which is kept in contact with the gland by action of the spring U. The driving pinion V, secured to the horizontal shaft, engages with bevel gear W that is keyed to vertical spindle D. The central spindle is hollow to permit the free exit of cuttings from the drilled hole.



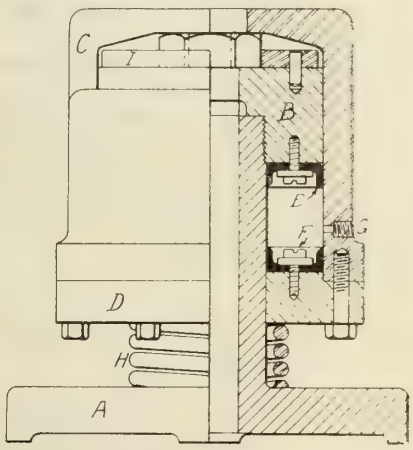
Drilling Eccentric holes in small round pieces.

AIR-OPERATED DRILL JIG

By J. H. R.

The more general application of compressed air to jig work is worthy of greater consideration from designers who are called upon to plan out fixtures for rapid handling of small pieces on an economic basis; particularly is this true where large quantities are being manufactured and the necessary machining takes but a short time when compared to the complete cycle of handling and tooling of the part.

The sketch illustrated shows a jig that was developed as a result of a similar one which proved very effective in machining a fuse part during the war. This jig was utilized for re-tapping a large number of nuts that had been re-



Air-operated drill jig.

claimed from scrap. The base A, which is bolted to the table of the drill press, carries the central post on which is screwed the top head B that constitutes the piston of the device. The cylinder or compression chamber is formed by the walls of the centre post and the outer shell, the upper part of the latter extending into three arms C with a central clamping ring. The leather washers E and F are secured on the pieces B and head D by means of six small screws. When air is released the spring H forces the outer shell and clamping ring upwards so that work may be easily removed. The ring I is doweled to head B, and may be replaced by others with the opening to fit other size nuts or irregular shaped work of any description within the range of the fixture. The air hose is connected at G. This device assures the thread being square with the clamping face of nut.

Care should be taken in the storing of grinding wheels. They are kept best when stored in dry places and it is desirable to stand them on edge in racks.

JIG AND FIXTURE DESIGN

By S. S. Moore

In the operation of jigs and fixtures rapidity of action is second only to the accuracy of the device in which the work is held. As in all other classes of machine shop work, the handling of the material and the time required to set the tools or attachments are the essential factors upon which efficiency is based; and it is therefore imperative that, apart from the actual machining of the piece, the period between operations—or the handling of the work—should be reduced to the lowest possible minimum. Where pieces are to be placed in jigs or fixtures for subsequent machining, it is very important that the clamping arrangement be of such a character that the pieces can be inserted and removed from position with minimum effort and loss of time. Various methods are adopted for holding work in fixtures during machining operations, the general practice being by the use of wing nuts or suitable cam clamps. While the effort required on the part of the operator is seldom such that actual fatigue results from work of this nature, it is often advisable to give due consideration to the conservation of the workman's energy even in those details that are invariably classed as insignificant.

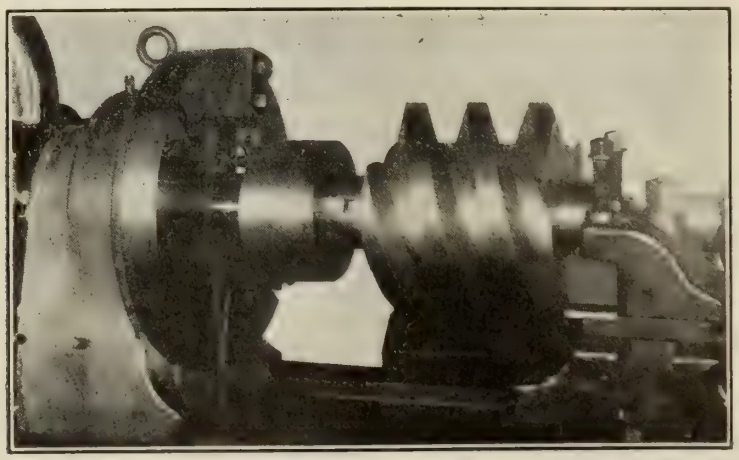
The possibilities of compressed air in the operation of jigs and fixtures should receive greater attention where rapidity of action goes hand in hand with economic production.

CUTTING LONG LEAD THREADS

By H. R. James

The chasing of screw threads having unusually long leads has very often been a perplexing problem and an undertaking that cannot always be accomplished on the ordinary engine lathe. A subhead has been developed by the Hendey Machine Co. that facilitates the cutting of coarse pitch worms on the common lathe without any addition of extra gearing. As illustrated herewith the device consists of a special head supported on the ways directly in front of the head stock, the faceplate being driven through reduction gearing from the nose of the spindle, the work being carried on a dead centre. The ratio of spindle speed to that of the work is 6 to 1. This arrangement provides for the cutting of a 6-in. pitch with the pressure on the lead screw the same as when ordinarily cutting a one-inch pitch thread.

The sub-head is designed so that it can be located in position quickly, two bolts only being required to secure it to the bed. By the use of two dead centres the work is carried in the same manner as in cylindrical grinding, thus increasing the finished accuracy of the work. The subhead can be adapted to the forming of special shapes, where it is necessary to use wide tools and slow speeds.

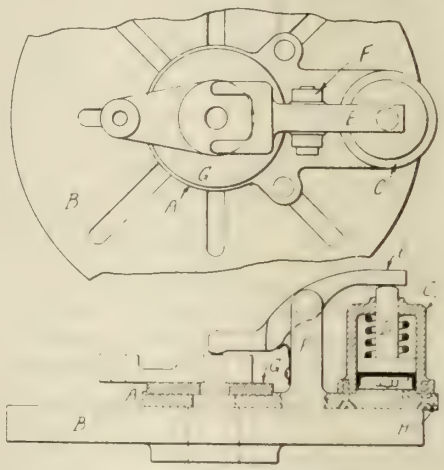


Cutting long lead threads.

PNEUMATIC CLAMPING DEVICE

By J. Garth

An interesting design of air-operated fixture is shown herewith. The jig is primarily intended for use on the drill press where light drilling is required, but may be used to advantage on a variety of machines or on bench work.



Pneumatic clamping device.

It will be seen that the jig is self-contained and may be used for many purposes. It is here shown fixed to a table of a drill press. The base A carries on one end the small cylinder C, held in position by screws shown. The air enters the opening H through the base of the fixture. The steel plate G is recessed into the base A and may, if desired, have a shape to suit any particular piece of work. In action the air forces the plunger D against the heel of the clamping lever E which is pivoted on the vertical piece F. The toe of the clamp is thus forced against the work. If desired, pin gauges may be located in the plate G. for accurate setting.

CLEANING OF MACHINE PARTS

(Continued from Page 24)

the pieces to and from the housing while retaining the abrasive within the enclosure and protecting the operator from dust and flying particles. An elevator and separator as in the barrel provide for cleaning and feeding the abrasive, making a continuous feed, self-contained unit. The installation of barrel and table together is frequently found advantageous.

Provision in all of these devices is also made for connection to the exhaust system, and it may be noted in passing that exhaust for the cabinet, barrel or table, or all in combination, with grinders as well where desired, can be connected to the exhaust-arrester system of the room installation.

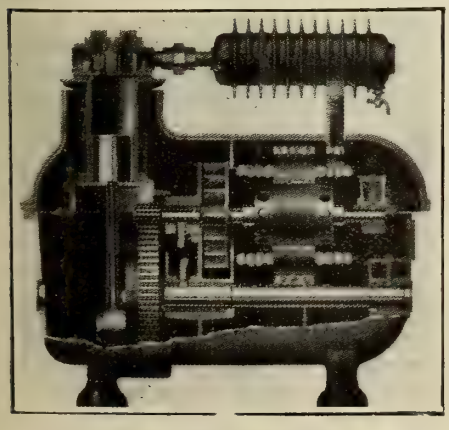
Saving Effected

The keeping of costs on this character of work seems to be fitted more in the breach than in the observance. This may be due to the fact that it may vary in different plants due to the individual conditions, and the fact that there are few plants turning out identically the same pieces. Another reason may be a disposition on the part of the manufacturer to keep these figures to himself, so that it is only in generalities that we can answer this question. For instance we have in mind a gas engine cylinder weighing upwards of eight tons that to remove the cores and clean the casting required two men fifteen hours, or thirty man-hours. With the sand blast cores were removed and the casting cleaned more thoroughly and more efficiently by one man in one hour. In a plant making roller-bearings the raceways have the bore ground on internal grinding machines. Sand-blasting these before grinding increased production on the grinding machines fully fifty per cent., due to removal of oxide scale in the treating furnaces, cleaning of which reduced glazing of the grinding wheels with less dressing required. Not only did production increase fifty per cent., but the working life of the wheels was materially lengthened. In another plant preparing metal for galvanizing where pickling had been previously used, a special sand-blast machine was designed and it is estimated that the first year's use will reduce operating cost by $25,000. Parts to be machined work faster, and as the sand-blast removes the outer scale or skin from the casting, which is most detrimental to the tool, saving in machining cost is effected which varies from fifteen to forty per cent. according to individual conditions.

New Things in Shop Equipment

ELECTRIC COMPRESSORS

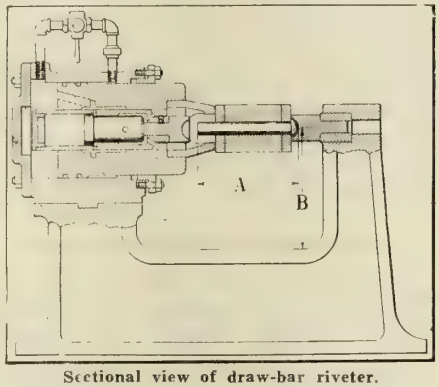
The accompanying cut shows a sectional view of a motor driven air compressor. It is built in two sizes, having capacities of six and twelve cu. ft. per. min. The former is capable of working up a pressure of 200 lbs. and the latter 75 lbs. pressure. The 2 h. p. motor is designed especially for this machine. The unit is self contained, motor gear-train and compressor being mounted in the one housing. Top cover is in two sections, individually removable. This permits of easy access to the interior mechanism. The removable cylinder head carries intake and outlet valves, both of which are arranged for pipe connections, so that the intake pipe may be used to bring pure, clean air to the compressor; this also makes it possible to use these machines for vacuum work by merely reversing the pipe connections. The valves are of automobile poppet type and ground individually to a perfect seat and tested under high pressure. The piston is of aluminum alloy, its light weight reducing inertia and vibration. Single reduction gearing is employed, the shafts running in extra large bronze bearings. The housing forms one big air jacket and a centrifugal fan on the armature shaft circulates air all through the housing and forces it out through opening under projecting flange of valve head, thus cooling commutator, windings, bearings, cylinder and valve head. The compressed air passes from the cylinder into a cooling and condensing chamber provided with fins to assure rapid dissipation of compression heat. There is no water to freeze up or evaporate. These electric air compressors leave the factory fully lubricated and ready to run. There are no coil cups to refill, nor any oil level to maintain. Grease is fed to all bearings through felt wicks by capillary attraction. Gears run in grease and cylinder walls are grease-lubricated by means of felt lubricating pad into which the piston is pressed slightly at the bottom of each stroke. On each up-stroke a thin film of grease is deposited on the cylinder walls. Minimum attention to lubrication is obtained by this system. Grease requires renewing only at three-month intervals. These compressors are made by the Black and Decker Mfg. Co., Baltimore, Ind.



Electric-driven compressor.

DRAW BAR RIVETER

The accompanying cut shows a sectional view of a draw bar riveter operated by compressed air, made by the Canton Pneumatic Tool Co., Canton, Ohio. This is used where railroad cars are built and it is for riveting yokes to car couplers. These rivets are usually 10 or 12 inches long and the plate closer presses the plates firmly together while the head of the rivet is being formed. This machine has two advancing cylinders, the larger operates the plate closer and the smaller, which works within the large, carries the piston and follows as the head of the rivet is formed. This machine is equipped with double acting cylinder so that the larger cylinder is returned by compressed air and as it is returning the smaller cylinder is carried with it. This device is used for testing heavy springs such as are used on trucks, etc., and if the spring bends or breaks, it is rejected. The advantage in using air for testing springs is on account of its quick action.



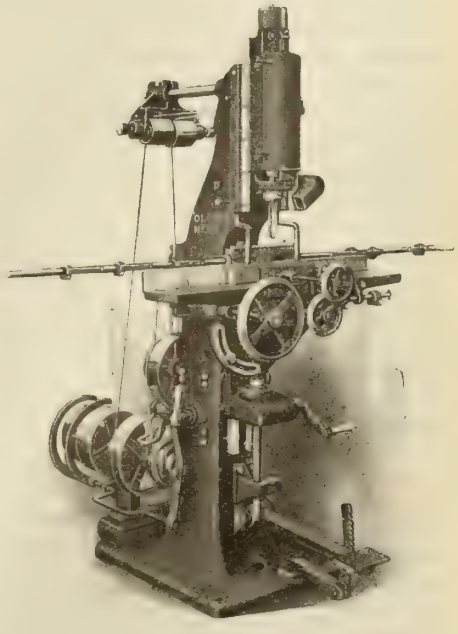
Sectional view of draw-bar riveter.

The piston has a weight of 8 lbs., the diameter of the ram being 10 in. The floor space required is 1 ft. 3 in. by 4 ft. 3 in. The machine has a capacity up to 1½ in. rivets, operates at a pressure of from 80 to 100 lbs., and weighs about 1,200 lbs.

HOLLOW CHISEL MORTISER

A power feed hollow chisel mortising machine designed particularly to meet the demand for greater production, and especially serviceable in factories engaged in multiple quantity manufacture of cabinets, furniture, sash and similar woodwork, has been placed on the market recently. A few of the outstanding features of this machine are the flexible power stroke, the quick return stroke, direct thrust support for the table and the efficient handling of the bit and spindle thrusts. It is speedy in operation, convenient to operate and compact in construction. The machine has a capacity of hollow chisels from ¼ in. to ¾ in. square. The stroke may be adjusted from 2½ to 4 in. Stock 6 in. wide can be centered beneath the chisel; 12 in. material can be mortised with 4 in. blades. The column is rigid and of hollow, box type pattern, made in one casting with wide flanged floor support. The power feed mechanism is enclosed within the column, the drive pulley being located outside.

The mortising ram or plunger reciprocates in adjustable gibbed ways and has a table travel of from 2¼ to 4 in., controlled by the foot treadle for single or continuous power feeding strokes. A swinging guard covers the spindle and the pulley affording maximum safety to the operator from revolving parts. The spindle is supported in self-lubricating bearings with special attention to taking care of end thrusts. The power feed mechanism is extremely simple and yet very effective. It is controlled by the foot lever and is brought into action by a belt tightener which, when released, brings a brake into action on the rim of the drive pulley. A ratchet is provided to hold the lever down for continuous feeding. The power feed has three rates of feed—18, 26 and 36 strokes per minute by means of cone pulleys and a feed belt shifter. By



Hollow chisel mortiser.

throwing out the ratchet the continuous feed mechanism may be instantly stopped and the machine operated by single strokes.

A universal compound table with screw clamp for 6-inch wide stock and hand wheel, rack and pinion for longitudinal travel, gauged by adjustable stops, is regularly furnished and very highly recommended as the most satisfactory form of table on machines of this type. Table is 36 in. long, 6 in. wide, 32 in. above floor at lowest position and 44 in. above floor at highest position. It is fitted with a vertically adjustable back fence which has a lip hold down and also carries a 6-foot layout stop rod with six spring stops for automatically locating mortises on the pieces. A rod and two adjustable stops directly in front of table govern the length of mortises. Two swinging hold down fingers which are held in the column of machine, project over the table and prevent work climbing up when chisel recedes.

The countershaft is supported on the base of the machine in adjustable bearings and has self-contained belt shifter with handle conveniently carried on column of machine. The machine is equipped with a 3 h. p. motor operating at 1,200 r. p. m. The floor space required is 3 ft. by 5 ft., and machine has a height of 6 ft. The mortisers are manufactured by the Oliver Machinery Co., Grand Rapids, Mich.

MOTOR DRIVEN BENCH GRINDER

A motor-driven bench grinder especially designed for use in garages and small machine shops has been placed on the market recently. This grinder is light and strong and particularly adaptable for tool grinding, wire-brushing, polishing and general utility work. The device is supplied with two 5 in. dia. wheels operating at a speed of 4,500 r.p.m., giving a surface speed of about 5,900 ft. per min. The wheel spindle runs in dust-proof parallel bronze bearings. The motor is of the universal type, driving the spindle through reduction gearing, the steel pinion on the rotor shaft meshing with a fibre gear on the wheel shaft. Long work can be ground parallel with the spindle without interference with the frame. The cover is close fitting and adequately protects the interior from dust and dirt. It is easily removed for inspection and adjustment. The height from base to wheel centre is 3 in. and wheels are 9¾ in. apart. The machine is shipped with complete attachments ready for installation. The weight of finished machine is 25 lbs. It is made by the J. A. Finley Co., Allston, Mass.

NEW NON-FERROUS ALLOY

A new metal alloy of the tungsten-chromium-cobalt class has recently been developed and it is claimed that remarkable speeds and endurance cutting tests on cast iron and alloy steels have been achieved. This metal is non-magnetic, contains no ferrous compounds, but has the appearance of steel. The metal is melted in electric furnaces and cast into molds of steel in the form of tool bits, twist drills, reamers, inserts for built-up milling cutters, etc. It is impossible to forge or anneal the metal and the only way to alter the shape is by grinding. The metal is very dense and is stated to be free from blowholes and internal strains, with a high resistance factor that makes it particularly adaptable to cutting metals. It can be given excessive rake and clearance angles. Standard sizes of bits for commercial tool holders are made and also heavy duty slabs or blocks welded to carbon steel shanks. This metal is marketed by the De Bats Sales Inc., Boston, Mass.

"KANT-SLIP" WRENCH

A wrench that is capable of gripping work of any shape and which will automatically adjust itself to any size within its range, has been placed on the market recently. There are no screws, pins or springs to wear out or break, and the fulcrum is always close to the load. The stationary jaw may be used as a hammer for light work, a flat at the back of the head being used for this purpose; a screw driver end is located on the handle of the wrench. It is claimed that the wrench can be used on any size pipe without damaging the pipe. This tool is made by the Allan-Diffenbaugh Wrench and Tool Co., Baraboo, Wis.

AMENDED CUSTOMS FORMS

Forms have been sent out by the Department of Customs and Excise, Ottawa, which embody the amendments to the act assented to in June last. These repealed the provision requiring appraisal on imports on the basis of the cost of production plus a reasonable profit and specify that the volume for duty on foreign goods shall be the same as on similar goods from the United Kingdom. Under the new requirements every invoice of goods entered under the general tariff must bear a certificate form by the exporter that each article in the invoice is bona fide the produce or manufacture of the country specified in the column provided for that purpose. It should further be noted that the present authorized certificate of the exporter showing the relative value in standard currency in paper currency of the invoice will be accepted by the Customs, subject to the usual verification by the Collector, on invoices of goods imported from a country the currency of which is not regarded by the Customs as substantially depreciated. The only countries whose currency is regarded by the Customs at present as being substantially depreciated are:—Germany, Austria, Hungary, Jugo-Slavia, Czecho-Slovakia and Russia. Invoices of goods from Austria, Hungary, Jugo-Slavia, Czecho-Slovakia and Russia are to bear thereon a currency certificate of a Consul, Canadian Trade Commissioner or Bank that on the date of exportation of the goods described in the within or annexed invoice the true value of the currency in which the invoice is made out as compared with the standard dollar of Canada is (at the rate of dollars .....cents.....) per ..... (unit of invoice.") This certificate is also required on invoices of goods imported from a country where currency has no fixed standard value. Collectors of customs are instructed that in cases where appreciation or depreciation of a currency is less than one per cent. the home consumption value on the invoice is to be computed for duty purposes at the par of exchange.

The new forms come into effect on and after Dec. 1st next.

BOOKLET

The B. F. Sturtevant Co. of Hyde Park, Boston, Mass., has just issued a new 72-page Engineering Bulletin on Pneumatic Collecting & Conveying. It contains 33 pages of pictures and diagrams, 17 pages of useful tables—how to find the size of fans, the suction, volume, r. p. m. and horsepower for any system, cubic feet of air handled per minute, size of pipe and ducts used, and various other valuable tables. Data are also given on dust collecting from grinding and polishing machines, tumbling barrels, sand blast machines, coal breakers, shoe machinery and the removal of fumes, gases, etc. In addition, there are parts on the conveying of pulverized coal, fibrous materials, coffee, ashes, wool, wood chips, etc., etc. It is a most comprehensive treatise on Pneumatic collecting and conveying systems.

EFFICIENT LUBRICATION

(Continued from Page 25)

cessive oil thereon, the quantity fed by the lubricators should be reduced. By thus examining the machine a few times, the proper amount of oil can be determined to suit the characteristics of the particular lubricant used and the conditions under which the machine operates."

Regular Cleaning

No matter how high the quality of the oil may be periodical cleaning should be consistently carried out to keep the walls free of carbon. Different methods are used to perform this duty but few, if any, will surpass the results obtained from the use of soap suds having the consistency of one part soft soap to fifteen of water. This mixture should be fed to the compressor through the oil inlet at about ten times the speed of the oil. This practice is advisable at least every two weeks, and during the process the air valves should be inspected to see the effect of the cleaning process and to act as a guide to the operator as to the quantity of solution to use. The machine should not be left after cleaning until it has been operating again for some time with the regular feeding of lubricating oil. This is necessary to prevent the possibility of corrosion.

Advances Agreeably Absorbed

SCARCELY a week goes by that there is not an advance, of more or less importance, in prices on the steel and metal markets. It is remarkable that these are being so easily absorbed by industry generally. In striking contrast are the protests of pre-war days when advances that would be considered slight to-day brought forth vigorous demands for investigation of the most drastic kind. Yet to-day, frequent advances of several dollars per ton seem to be accepted as an essential of the industrial record. It may be that extraordinary circumstance is responsible, as in the jump of $10 per ton in the price of pig iron in the past two months, due largely to strikes. During the war and subsequently, these things carried with them something of the inevitable. It would seem indeed, that repeats of this kind tend to wear down that sense of protest which, in the piping times of peace, was very easily aroused. Nevertheless, some very peculiar mental slants are encountered. Advised that they would have to pay more for their pig iron, their bars or sheets, there are buyers who have quite seriously declared their approval and soberly express hopes that prices would go higher. Such an attitude might reflect a conviction that higher prices mean better business or the elimination of an undesirable feature of competition in the finished article, or as assisting in a plausible explanation of advances more or less essential in the manufactured article.

* * * *

Would Stabilize Coal Industry

PERIODIC warfare and futile attempts at solution in connection with the coal industry in the United States, have at last developed a problem which is to be submitted to a commission appointed by the president. Various conferences in official circles have brought out several proposals by way of probable solution. It is pointed out that larger storage by the railways at times when the public demand is slack would overcome competition by the railways with the public for coal. Larger storage by public utilities is suggested, also that co-operative marketing after the system developed by farmers' organizations might reduce distribution costs. It is evident that one of the chief causes of trouble is the instability of employment, and strained relations between employer and employee as the result of this intermittence. Under such conditions, the principle of collective bargaining to which some improvement in the conditions of employment may be ascribed, breaks down and strike follows strike. Minorities of speculative operators and narrow-minded labor leaders oppose constructive policy desired by the better element on either side, with the result that there has been constant warfare.

"Organs" Waste Advertising Funds

THAT AN association should be that only and not pretend to give service to advertisers is the important principle which has been adopted by the Associated Advertising Clubs of the World in regard to "Associated Advertising" which in future will not sell space. This decision by an organization of leading American financial, manufacturing, mercantile and other business concerns is a highly important one in the field of advertising and publicity.

Congratulations to the Associated Advertising Clubs in taking this stand, are offered by Printers Ink which points out that the Clubs "can now take a fearless stand in their opposition to nondescript mediums which are organized and conducted solely for the purpose of producing revenue and for which there is no real need in the field."

Particular emphasis is laid upon Trade Associations as offenders in this respect: We read:

Trade associations have been our greatest offender in this respect. Advertising-soliciting organs of this sort are started for many reasons, but generally with the hope that the revenue thus raised will help to defray the expenses of the Association. Thus the organization launches itself into a separate outside business about which it knows nothing and which it conducts merely as a side-line. The fact that in most cases these publications are money-losers does not deter others from trying to be the exception.

From the advertiser's standpoint, the greatest objection to nondescript mediums is that they subtly dissipate appropriations. In one guise or another, these mediums levy peremptorily on the advertiser's funds and thus exhaust appropriations, leaving the advertiser with the mission of his selling campaign unaccomplished. This is one of the most crying evils in advertising. The Clubs, and in fact every legitimate advertising interest, should join hands to stamp it out.

* * * *

Railways Are Buying

REMARKING upon general market conditions and tendencies, an authority declares that business is being booked for requirements of the immediate future, that forward buying is cautious, and that it is hardly reasonable to expect a boom although the underlying tone is most encouraging. Recent buying by the national railways for their machine shops was welcomed in a market which for some weeks has been almost featureless. It is hoped that this is the forerunner of other buying activities on the part of the railways, for in appraising the possible sources of business the machine tool dealer and manufacturer may be said to have had his ear to the rail for some time. Much industry depends upon railway activity. Busy, well-equipped roads and shops indicate basic prosperity.

Steel Tonnage for Canada Double that of Last Year

Hoops, Bars, Plates and Structural in Demand—Reflect Industrial Activity—Dealers Declare Growth Healthful Rather Than Spectacular—Steel Rail Advance, Oct. 1, May Bring Railroads Into Market—Non-Ferrous Situation Discussed.

WILL PRICES DECLINE OR HOLD ADVANCES?

WITH A temporary cessation of price advances, the next question that arises, is: Will the market remain stationary or will it decline? Certainly reports from Pittsburgh show that production is increasing and at the same time buyers show a reluctance to make commitments for the distant future, say December or the first quarter of next year. Some advance buying is being done, but it cannot be regarded as representative of the market. At the end of August steel mill operations had declined 50 per cent., while at the present time the increase is equal to 65 per cent. These increases do not indicate a uniform movement, but it shows to what extent furnaces are being blown in.

Transportation, however, is still the big problem, and shipments at best are irregular, although it is considered significant that several of the independent steel interests can now make shipment on new orders, in about thirty days. Pittsburgh declares it is not unlikely that in view of the attitude taken by buyers and that the dull period which comes with the year end is not so far distant, premiums of $3 to $5 per ton as a guarantee of shipment within reasonable time, will fade away altogether.

That tonnages of steel imported for Canadian industry have been double that of the same period last year is the statement received from large steel interests on this market. It has been a steady increase indicating sound underlying conditions, and this is borne out by the statements of dealers who point out that there has been nothing spectacular in the development and that it represents healthful growth. It is felt that, in spite of conservative tendencies, stocks have accumulated at lower prices. In fact, it is known that there was heavy buying in many quarters in anticipation of recent advances.

Spot buying is a feature of the pig iron situation. Supplies are limited and prices high and it is not surprising that buyers should indicate an inclination to look for lower quotations. Pittsburgh reports that "pig iron is stagnant; consumers apparently are unable to pay prices asked, while if they bought any considerable tonnage, prices would advance."

The recent advance of steel rail prices from $40 to $43 per gross ton by Oct. 1, may bring the Canadian railways into the market to cover temporary requirements before that time. It follows that an increase by the Steel Corporation means a similar movement in Canadian mills. It may be that recent orders executed for Canadian lines were in anticipation of present conditions.

Montreal reports that each month this year has shown an increase of about 10 per cent. over that preceding. Steel prices are firm, pig iron is scarce and structural sections slow in August show a marked recent improvement. Some fairly large steel orders have been placed with British mills. There is very little to choose from in deliveries for this or Pittsburgh sources. Machine shops are reported to be coming into the market for a fairly large quantity of material.

Toronto

September 27

STEADY business with no spectacular tendencies, is the character applied to the iron and steel market by dealers and manufacturers. The third quarter, now drawing to a close, has shown little change on the whole as compared with the two preceding, but the record shows that the demand has been a steady one with no breaks or booms that would indicate unhealthy conditions. Although buying does not indicate a strong tendency to anticipate future requirements, it is felt, nevertheless, that there has been quiet accumulation of stocks by those in a position to read the trend of affairs. It is regarded as certain that, while price advances are at their peak for the present, they will remain firm until well into next spring, and some buyers have anticipated this in their purchases. While local dealers, therefore, state that progress has been made along national lines, and that the outlook is encouraging, import interests representing large corporations declare that tonnages on structural, bars, hoops and plates have been exceptional, in fact, double that of last year. The increase from $40 to $43 on steel rails effective Oct. 1, announced by the U. S. Steel Corporation, may bring a rise out of Canadian roads to cover their requirements by the date specified. Although Algoma rail mills are not operating, development of business of this kind could be taken on, as it is only recently that they closed on completion of a rail order for Canadian lines.

Scrap metal markets have been somewhat characteristic of the market, demand and supply pursuing a somewhat even tenor with prices quite stable. In a sense this is a department which comes into close quarters with industrial activities generally, and reports declare the outlook to be encouraging and that evidences of depression are lacking. Prices follow:

Copper, light, per 100 lbs.	9 00
Copper, crucible	11 50
Copper, heavy	11 25
Copper Wire	11 25
No. 1 compositon	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 25
Light brass	4 50
Medium brass	6 00
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton.	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine castiron	18 00
Pipe, wrought	7 00

Non-ferrous metals continue to reflect varying influences but nothing that gives outstanding character to the market. Copper is said to have shown the depressing effect of war news, but the situation is described as firm. Tin values have also dropped; spelter will probably go higher, while lead is firm. Commenting on non-ferrous metal markets E. W. Knight of Frankel Bros., Toronto, had this to say:

"**Copper.** This market has suffered from the somewhat depressing effect of the war news, and also from the less satisfactory tone of the labor situation, both here and in the States. In addition, a great many works in the United Kingdom have closed down, and have requested that copper actually purchased here be held until further instructions are cabled.

"Actually there is no change in the situation, and unless the war clouds hovering over Europe develop into something more tangible than at present seems probable, no actual change seems likely. There will likely be flurries, and possibly some panic, and if this occurs it is pretty hard to say just what will happen to the market. It will likely cause spasmodic trading for a few weeks, with the market eventually settling at the present level of 1 cent, New York, or 17 cents, Toronto.

"The statistical position of the metal is sounder than has been the case for some time, and the situation is now on a firm basis. Personally I do not see any reason to change the views previously expressed, and I am under the impression that little alteration will take place this year.

"**Tin.** The outlook for tin is more promising than for some time, but values have sagged in sympathy with other metals. The same remarks as are applied copper, apply to tin, which accounts for the weakened condition of the market. There is a heavy demand for tin plates, and this is bound to be felt before many weeks are over. Very little speculative support has been given the

market in the last two weeks, but if the European situation improves, an advance is quite likely. The bulk of the buying is for prompt shipment, and little or no interest is shown in futures.

"**Spelter.** This metal is on the jump, and shows every indication of higher, and yet higher prices. Stocks are held in strong hands, and it would appear to be good policy to lay in present requirements.

"**Lead.** This market is firm and strong, and a great deal of speculative buying is taking place, but these things, notwithstanding, there does not appear to be any adequate reason why lead should advance beyond present levels.

"**Zinc.** This metal is in a stronger statistical position than at any time since the end of July, when 632½ East St. Louis was paid. There has been a very brisk demand from galvanizers, and brass mill purchases have also exceeded expectations. This market appears to be heading for higher levels, and consumers would do well to lay in stocks as soon as possible."

Local prices follow:

Lake copper	17 25
Electrolytic copper	17 00
Castings, capper	17 00
Tin	36 00
Spelter	8 50
Lead	7 00
Antimony	8 50
Aluminum	23 00

Bars and sheets while reporting a fair demand, show quite a stable price position, with the range from $3.25 to $3.40. The recent movement to establish the higher figure as the basis was not long lived, and whatever else may be said about Toronto markets, one thing is certain, unison on a maximum price will be a difficult, if not impossible proposition, so far, at least as bars are concerned. At the present there are two camps those who hold that a spread of $1.25 as between Pittsburgh and Toronto is by no means sufficient, cost of doing business being considered, while on the other hand there are those who feel that the spread of $1.25 represents a fair profit on a good customer, but that circumstances are always a factor for consideration and hence they prefer to maintain an independent leeway.

Sheets are a firm feature, with quite a lot of spot business offering. Some big buyers, reporting a shortage, have appeared on local markets for supplies to tide them over until shipments arrive. The rather pronounced upward swing in prices is recognized as having a stabilizing influence and that for first quarter, at least, there should be some strong buying by manufacturers who know they must have the goods. Local prices follow:

Iron bars	3 25	3 40
Steel bars	3 25	3 40
Reinforcing bars	3 25	3 40
Steel hoops		4 75
Tire Steel		3 50
Spring steel	7 00	14 00
Band steel, No. 10 gauge and 3-16 in base		3 90
Small shapes		3 50
Sheets, black, No. 28		5 50
Sheets, blue ann., No. 10		4 50
Canada plates, dull, 52 sheets		5 75
Canada plates, all bright		6 75
Galvanized Sheets, No. 28		6 75

Cotton ducks, 6 to 12 ounce have advanced from 1¼ to 2½ per lb. while Yarmouth army ducks advance 1¾ cents per lb. Plumbers' oakum is now quoted at $6.00 per cwt. a decline of 30 cents.

Toronto pig iron markets have as yet developed no remarkable demand indicating shortage among the foundries. There has been some spot buying, but the trade is evidently adopting a conservative attitude as to prices.

The advance from $40 to $43 a gross ton recalls that when the war demand for steel was at its peak, the highest price paid for steel rails, Pittsburgh, was $55 for Bessemer and $57 for open hearth during the months when the war demand for steel was at its peak. With the ending of the war and subsequent cancellations of contracts the market became an open one, the Steel Corporation and independent makers arriving at prices of $45 for Bessemer and of $47 for open hearth rails as a fair estimate of the situation. Reduction of rails to $40 last year came at a time when the steel market was greatly perturbed by the wave of depression and prices were fluctuating considerably. The announcement of the corporation at that time was regarded as a long step toward price stabilization.

Since the advance by the Steel Corporation in the wage paid to day labor, an advance which was promptly met by all the independents, there has been a tendency to mark up prices on the lighter steel products. Uncertainty surrounding the coal situation this winter and next spring also has been a factor in the price unsettlement during the last few weeks.

Montreal

September 27

FIGURES for the total volume of business handled by the local jobbers in the iron and steel lines for the month of September will show an increase over August, according to the advance information given out locally. Roughly speaking, each month throughout the calendar year has shown an increase of approximately ten per cent. over that of the previous month. Thus it is seen that the volume of business that existed in January is only about half of the volume moving at the present time. Steel deliveries are growing a little more distant each week and the prices are firm, and in some cases a slight advance is noted. The strike situation is clarifying itself slowly but the results will not be overcome for some time to come. Steel products are moving somewhat better than last week. Pig iron is still very scarce, most companies being reluctant to take on new business. The supply of pig iron from British sources is pretty well booked ahead, and chances of any large importation before the close of navigation, are small. Machine tools are not active, although the supply business keeps up fairly well. The nonferrous metals were quiet during the week. The scrap metal markets show an activity which is better than has been noted for some time past.

Iron and Steel. The demand for steel products has shown a very satisfactory improvement during the past few weeks. Prices are firm, the mills quoting $2.60 base to the large consumer, and $2.70 base to the jobber and contractor. The jobber is quoting to the small consumer $3.35 base. Merchant bars are not moving as well as they were a few weeks ago. On the contrary structural sections that were rather slow movers in August, have shown a marked improvement lately. Most of the specifications, however, are for out-of-town jobs. The city demand is rather quiet. Plates have had but little sale all season, but have recently started to move at a very satisfactory rate. Deliveries of plates from the Pittsburgh district on preferred orders, run from three to six weeks.

Quotations on British steel, delivered Montreal, are such that there is very little to choose between them and the Pittsburgh steel delivered Montreal. In the case of deliveries, the British firm can make shipment ten days to two weeks after receipt of orders, and it is invariably the case that the steel is on the dock at Montreal under six weeks after an order has been mailed from this side. Some fairly large orders have been placed with British mills recently.

Galvanized sheets are still in good demand. For some months the supply was barely able to take care of the demand. Some jobbers have been able to accumulate a fairly good stock while others are continually sold out of the standard sizes and gauges. Practically all of these galvanized sheets are imported from British mills.

Blue annealed sheets and black sheets are also moving well but not in the same measure as the galvanized sheets. The seasonal autumn demand for sheets is commencing and there will be a heavy movement of all classes of sheets from now on till the end of the year.

Small steel products such as nuts, bolts, spikes, etc., are moving well. Miscellaneous steel products such as reinforcing bars, spring steel, tire and band steel, etc., are also moving freely. The local mills are doing a fair business supplying the jobbers in the city. In spite of the unsettled outlook the business moving is very satisfactory. Local quotations are as follows:

Iron bars, base	3 15 to 3 25	
Steel bars, base	3 15 to 3 25	
Reinforcing bars, base	3 15 to 3 25	
Steel hoops		4 25
Tire steel	3 25 to 3 40	
Spring steel		7 00
Band steel, No. 10 gauge and 3-16" base	3 65	3 75
Small shapes	....	3 40
Sheets, black, No. 28	....	4 40
Sheets, blue ann., No. 10	....	4 05
Canada plates, dull, 52 sheets	....	5 50
Canada Plates, all bright	....	7 00
Galvanized Sheets, No. 28	....	6 50

Pig Iron. During the past ten days the supply of pig iron available for export from the British producers has been pretty well booked up. This fact has only tended to make more acute a rather awkward condition. Practically no Buffalo, or other U. S. iron is quoted for export. Heavy shipments of pig from Britain to the United States have cleaned up all the surplus there. Local pro-

ducers are short of coal and cannot book any more business until a further supply of coal and coke has been assured. Prices on Canadian iron are slightly over forty dollars a ton for the No. 1 iron. It is now shown that only a limited tonnage of pig can be shipped into Montreal from the Scotch furnaces before the close of navigation. In some quarters it has been stated that the ocean tonnage available for the carrying of such products, are now all engaged in carrying coal or have been chartered to carry the iron for orders that have already been placed. A shipment of Carron iron reached the city recently. It is quoted at $35.00 a ton in carload lots on dock. Jobbers have placed orders for a few small lots of Middlesboro and other British iron, securing same whenever price and delivery were attractive. Summerlee iron is quoted at $35.00 per ton in carload lots on dock. The local foundries have their nominal requirements pretty well covered, and although they would come into the market if iron could be secured at a reasonable figure, it is not felt that any shortage will develop. In some cases it will mean running pretty close to the hand-to-mouth principle. Local quotations are as follows:

Algoma, No 1, car lots on tracks, nominal quotation	40 50	....
Summerlee, 5-ton lots, warehouse	40 50	....
Summerlee, 30-ton lots, dock	35 00	....
Carron, 30 ton lots	35 00	....
Do., 5 ton lots, ex. warehouse	40 50	....

Machine Tools and Shop Supplies. Practically no change has occurred in the machine tool situation. Machine shop activity has not increased to such an extent that all the idle equipment is in use. For that reason it is practically impossible to interest shop owners in new equipment. Sales are usually for single small machines. Wood working tools still continue to lead the iron working tools in the volume of business moving.

The supply business continues to be very satisfactory. The shops are coming into the market for a fairly large quantity of material. Prices remain, on the whole, stationary, although there are continually small changes in discounts coming through. Prices on steel having risen, has tended to make prices on supplies rather firm in some cases.

Non-ferrous Metals. Very little activity has been manifested in the non-ferrous metal markets during the week. About the same amount of business is moving while prices remain practically unchanged, except in the case of lead and antimony, where slight advances were recorded. Orders are well scattered. Local quotations are as follows:

Lake Copper	17 75
Electrolytic Copper	17 50
Castings, Copper	17 25
Tin	35 50
Lead	7 50
Spelter	8 75
Antimony	6 75
Aluminum	22 00

Scrap Metals. The scrap metal market continues to show a slight improvement, as well as a manifestation in stiffening quotations. The iron market is more active than non-ferrous metals as the shortage of pig locally has led to the better demand for heavy scrap. The non-ferrous metals are a little more active than they have been during the last few weeks. The local quotations are as follows:

Copper, light ..... per 100 lbs.	9 00
Copper, crucible	11 50
Copper, heavy	11 25
Copper Wire	11 25
No. 1 composition	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 25
Light brass	4 50
Medium brass	6 00
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine cast iron	20 00
Pipe, wrought	7 00
Car wheels	17 00
Steel Axles	15 00
Machine shop turnings	4 00
Stove plate	16 00
Cast boring	4 00

Pittsburg

September 27.

IT HAS become very plainly evident that, in general, price advances in the steel market are ended for the present at least. In prices actually being quoted and paid there is no decline, but underlying conditions are making for either a stationary or a declining market.

The two important underlying conditions in this connection are the increased production and the complete unwillingness of the average buyer to make commitments for the more distant future, say for December or the first quarter of the new year. There is some buying for such deliveries, but by comparison with the general run of steel business being put through, such buying is properly classed as exceptional rather than typical.

The average of steel mill operations has increased from the low point of 50 per cent. at the end of August, to nearly if not quite 65 per cent. at the present time. The increases have been variously distributed, being nothing like uniform among the different producers. As to the Steel Corporation, it has had a large increase in the Chicago district, but little if any increase in the Pittsburgh and valley districts. Among independents, the Jones & Laughlin Steel Company, Pittsburgh, has had the largest increase. This company was operating six of its 12 blast furnaces at the beginning of August and got down to three by the end of the month, while now it has eight stacks on and is planning to blow in two more. Aggressive efforts to sell are naturally to be expected in this quarter. The Cambria Steel Company, Johnstown, Pa., has also done well, so well that it is understood it has lately been offering some pig iron in the open market, apparently having a surplus over the requirements of its steel making departments. The Youngstown independents have done moderately well in resuming, by comparison, but they were at a very low operating rate at the end of August, and they are very far from a full operation at the present time.

Car Shortages the Rule.—Operations, of course, depend on fuel supplies, and fuel supplies in turn depend upon transportation, not upon coal mining capacity. Naturally there are great differences in the facility with which coal can be moved between different points. The rapid resumption by the Jones & Laughlin Steel Company is due to the fact that it moves its coal by water from its own mines. Especial mention should be made of conditions in the Connellsville region. The strike is still on there, in that there are thousands of idle men there who consider themselves on strike, yet as to the production of the region in general, it has lately been up to the limit of railroad transportation, as car shortages have been the rule for a fortnight. There are thousands of men working in the Connellsville region who never worked there before. Not a few of them are of African descent. This does not present the whole picture, however, for the Steel Corporation has many mines in the region which normally ship coal by water to the great by-product plant at Clairton, also to points where the coal can be transferred to cars. More coal could be moved from these mines if there were more men at work.

In the trade it is considered a very significant fact that several of the independent steel interests can now make shipment on new orders in about 30 days. In nails, still earlier shipment is possible, also of course, in tin plate, which is out of season. In pipe, on the other hand, all the mills are far behind.

Price Movements Change.—Before the war the market price of a steel commodity was always clearly defined. There was only one price, except that at times premiums had to be paid to secure particularly early delivery. Such premium prices, however, were regarded as irregular, the late delivery price being everywhere regarded as the real market. Since the war the case has been different. When there were two prices there has been a question which was the regular price and which the exceptional. In 1920, for instance, the Steel Corporation held its prices down to the Industrial Board level, allocated its tonnage, and could not make anything like early delivery on new orders. Independents secured much higher prices, sometimes double, and many observers considered the independent prices as the real market.

From say the middle of March to the end of August, there was a rising market, independents advancing first and the Steel Corporation afterwards. A month ago the common view seemed to be that the independent prices represented the real market, that whatever price the independents established the corporation would eventually get up to, so that the corporations quoting a lower price represented a temporary and exceptional condition.

(Continued on Page 16)

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

PIG IRON

Toronto price:—

Silicon, 2.25% to 2.75%	39 30
Algoma, No. 1, Montreal,	40 80
Summerlee, Scotch, Montreal dock	35 00

News From the Industrial Field

Beacon Electric Mfg. Co., Limited, Hamilton, has been incorporated with $50,000 capital to manufacture electric goods.

Electric Sales and Engineering Co., Limited, Fort William, has been incorporated to deal in and manufacture hydraulic and electrical equipment.

Keith Electric Refrigerator Co., Toronto, have been incorporated to manufacture refrigerators and refrigerating plants and appliances.

Fedders Mfg. Co., Limited, Bridgeburg, has been incorporated to manufacture automobile radiators, engines, boilers, tools, etc., with working capital of $50,500.

Pittsburgh reports indicate that coal prices are showing weakness. Run of mine coking coal is obtainable at $4.75 and steam coal at $4, a drop of fully $3 from the cost of one month ago.

The ten principal products of the mineral industry in Canada during first half of the present year in order of the values assigned were: Coal, $24,346,959; gold, $12,110,242; silver $5,997,199; lead, $2,882,047; natural gas, $2,448,829; copper, $2,337,093; asbestos, $1,894,232; nickel, $1,401,820; zinc, $1,370,460; and salt, $849,133.

Effective Oct. 1, the U. S. Steel Corporation has increased to $43 a gross ton the price of steel rails. This also covers deliveries for the first half of next year. The present price of $40 a ton announced in Oct. last, represented a reduction of $7 per ton from the level obtaining from March 1919, until that time. The increase is largely due to rise in rate of wages for day labor.

Industrial operations are again normal in the Ford plants and those associated concerns that were closed down on Sept. 17 as a protest against the high price and non-delivery of coal. At midnight on the morning of Sept 22, most of the plants affected were again working. Edsel Ford has made arrangements for a supply of fuel for continuous operation of all his factories.

When the United States Steel Corporation was granted a contract for steel rails for Glasgow, because their tender was £2,900 below that of British firms, labor took exception claiming that conditions of labor in the American industry were not satisfactory. It was pointed out in reply that the hours ranged from eight to ten hours and that as an indication of wages earned it was becoming quite a problem to provide space in which to park motor cars owned by the employees at the works.

From Washington comes a prediction by Secretary of Treasury Mellon, that a sharp expansion in industry and business may be confidently expected with end of coal and rail strikes.

The annual meeting of the American Electro-Chemical Society was held in Montreal during the past week. Many interesting papers in connection with electric heating were read and discussed.

Montreal.—Officials of the Eugene Phillips Electrical Works announced that construction would be commenced at an early date on the second manufacturing unit of the company's plant at Brockville. This unit will be the power cable mill.

A chain drive installation, said to be the largest in any grain elevator in the world, was recently placed in the Northern Central Elevator at Baltimore. This drive was one of 7,000 h.p. and made by the Morse Chain Co. Similar drives of approximately the same h.p. are located in other elevators in Canada and the United States.

A rail sawing plant which will employ from 20 to 30 men has been installed in the G. T. R. yards, Belleville. The object of the plant is to saw off battered end of rails, redrilling them, and replacing them upon the tracks. The only other plants of a similar nature on the line of the G. T. R. are located at Montreal and London.

Advices from London state that 300,000 tons of pig iron were shipped from the Old Country to United States since April 1, the beginning of the coal strike. Great Britain in August had an output of 411,700 in pig iron, an increase of more than 12,000 tons over preceding month. The number of stacks in operation increased from 117 in July to 126 in August.

Canadian mining men who have been urging the payment of a government bounty to encourage the development of the country's iron ore resources, will be interested in knowing that the union parliament of South Africa recently provided for the payment to any iron or steel company within the Union of South Africa, which provides plant and machinery capable of producing an output of 50,000 tons of pig-iron or 50,000 tons of steel per annum, of a graduated bounty, which will come to an end after eight years. For the first three years (1924-25 to 1926-27) the bounty shall be 15s. per ton for pig-iron and 15s per ton for steel. It then drops in succeeding years to 12s 6d., 10s., 7s. 6d., 5s., and (1931-32) 2s. 6d. per ton, thereafter terminating.

J. F. Letz, formerly with Michigan Optical Co., Detroit, has been appointed manager of the Interchangeable Counterbore Co., Walkerville.

Creelman's Limited, Georgetown, were recently incorporated with $200,000 capital, to manufacture knitting machinery of all kinds. Among the provisional directors are mentioned R. J. Creelman, and C. E. Creelman.

Port Arthur, Ont.—The Thunder Bay Company purpose to increase the output of its groundwood plant here to 100 tons a day. A paper mill unit capable of turning out 60 tons a day will also be constructed, it is said, if a suitable timber limit can be secured in the Nipigon forest reserve.

Hartville, N. S.—The Premier Paper and Power Company is preparing to install a standard newsprint machine in its plant at Hartville. The machine will have a capacity of 15,000 tons a year. In order to provide the necessary power the company is making an additional development of 5,000 horse-power on the river.

Regina, Sask.—Construction of two giant oil tanks is planned by Imperial Oil Co. on the 40 acre tract of land adjoining the Regina plant, which was recently purchased by that company. These containers will be the largest of their kind in Canada, if not on the continent. Each will have a capacity of over 90,000 barrels of oil.

Vancouver, B. C.—Returns made to the Provincial Government by 2,275 individual industrial firms in British Columbia, indicate that a total of $79,742,820 was paid in salaries and wages to employees last year, of which $65,314,624 was paid to wage-earners. The total paid out shows a reduction as compared with 1920, when more than $82,000,000 was expended.

According to iron and steel statistics from Washington, Canada was the foremost buyer of American material, in July taking 48,010 tons out of a total of 159,338 tons exported. Canada's purchases included 8630 tons of ingots, blooms, billets, sheet bars and skelp, 6427 tons of iron and steel bars and rods other than wire, 3808 tons of iron and steel plates, 5780 tons of structural material, 3526 tons of black steel sheets, 3101 tons of galvanized sheets, 2369 tons of steel rails, and 1899 tons of hoops, bands and strips. Japan, which was the second largest buyer in July, took 16,886 tons of steel rails, 8153 tons of black steel sheets, 2746 tons scrap iron and steel, 1339 tons tin plate, 1330 tons rail fastenings, 1284 tons of bars and rods, and 1210 tons of structural steel.

Unemployment at Sault Ste. Marie this Fall may call for more than normal action, and the city council may purchase a bush and set the unemployed to work cutting wood for the city.

Canadian railway Shopmen have expressed a desire to re-open direct negotiations with the companies on the question of wage rates. The conference may be opened next week.

Showrooms for Canadian products may be opened shortly in Shanghai, China, by the Department of Trade and Commerce. Manufacturers entering the exhibit may be asked to supply their own salesmen. If the plan is successful, it may be adopted in other countries.

By the use of electric steam generators in the Laurentide Paper Mills and the Belgo-Canadian Pulp and Paper Co.'s plant in the St. Maurice Valley, four hundred tons of coal are saved daily. Unlike other systems of generating steam, the off-peak hours can be utilized for this purpose.

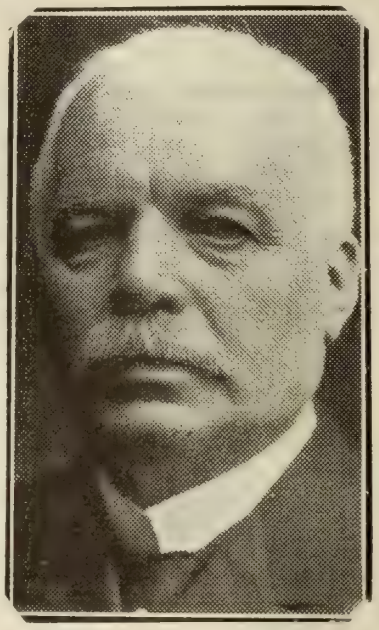
Regina, Sask.—Exceeding all previous figures forecast by various authoritative bodies this year the Manitoba Free Press in it nineteenth crop report estimates the wheat yield of the Prairie Provinces this year at 371,910,000 bushels from a total acreage of 21.471,000, giving the West the greatest wheat yield in its history. Other estimated yields are: oats 413,539,000 bushels; barley 61,080,000 bushels; rye 54,311,000 bushels; and flax 3,088,000 bushels.

Welland, Ont.—Another American firm has established a branch factory in Canada. The Dodds Canadian Iron Works have been incorporated with a capital of $200,000, for the purpose of manufacturing flour machinery. The Dodds Brothers have been engaged in the manufacture of flour mills in Decatur, Illinois, for the past couple of decades and the demand for their product has become so great in Canada that it was necessary to install a plant here in order to supply the market.

That the Birmingham, Eng., area should be considered as a market by Canadian manufacturers of rivets, nuts and bolts, is the suggestion made in a trade report, which adds: "Up to now Canada has not been able to compete with bright bolts and nuts, and still cannot. The sizes mostly in demand are ¼ inch up to 1-inch. The business is done on a 2½ per cent. discount basis. There seems no reason why Canadian manufacturers should not be able to secure a larger amount of business in these lines than in the past. Quality here will aid in the battle against European competition. With a good live agent on the spot a more aggressive attack can be made by the mere filling of spasmodic orders. Canadian spelter for galvanizing is in demand. The price is of course a fluctuating one in accordance with the supply and demand on the market."

OBITUARY

W. F. Johnston of Toronto passed away at his home last week after a long illness. He was born near Port Hope 72 years ago. During his early life he was associated with the Massey Manufacturing Co., of Newcastle, Ont. Some years ago this company was merged with the Massey-Harris Co. of Toronto.



THE LATE W. F. JOHNSTON.

He is said to be the last survivor of the former company of those associated with it at the time of the initial organization. For many years he was general superintendent of the Massey-Harris plant in Toronto. Mr. Johnston resigned from this position about 20 years ago to become managing director of the Noxon Co. of Ingersoll, Ont. Twelve years ago he retired from active business, since living in Toronto.

In the merger of Bethlehem and Lackawanna Steel Corporations it is evident that Buffalo is to be made an important center of selling operations, comprising as it does the important western New York territory, with which is included the important industrial section of Canada. In a recent statement Eugene G. Grace, president of the Bethlehem, said:— "We consider Buffalo an important commercial center, and we expect to develop an important selling office in that city to serve that district. It will be our policy to use as many of the present officers and managers of the Lackawanna Steel Company as possible in the combined organization."

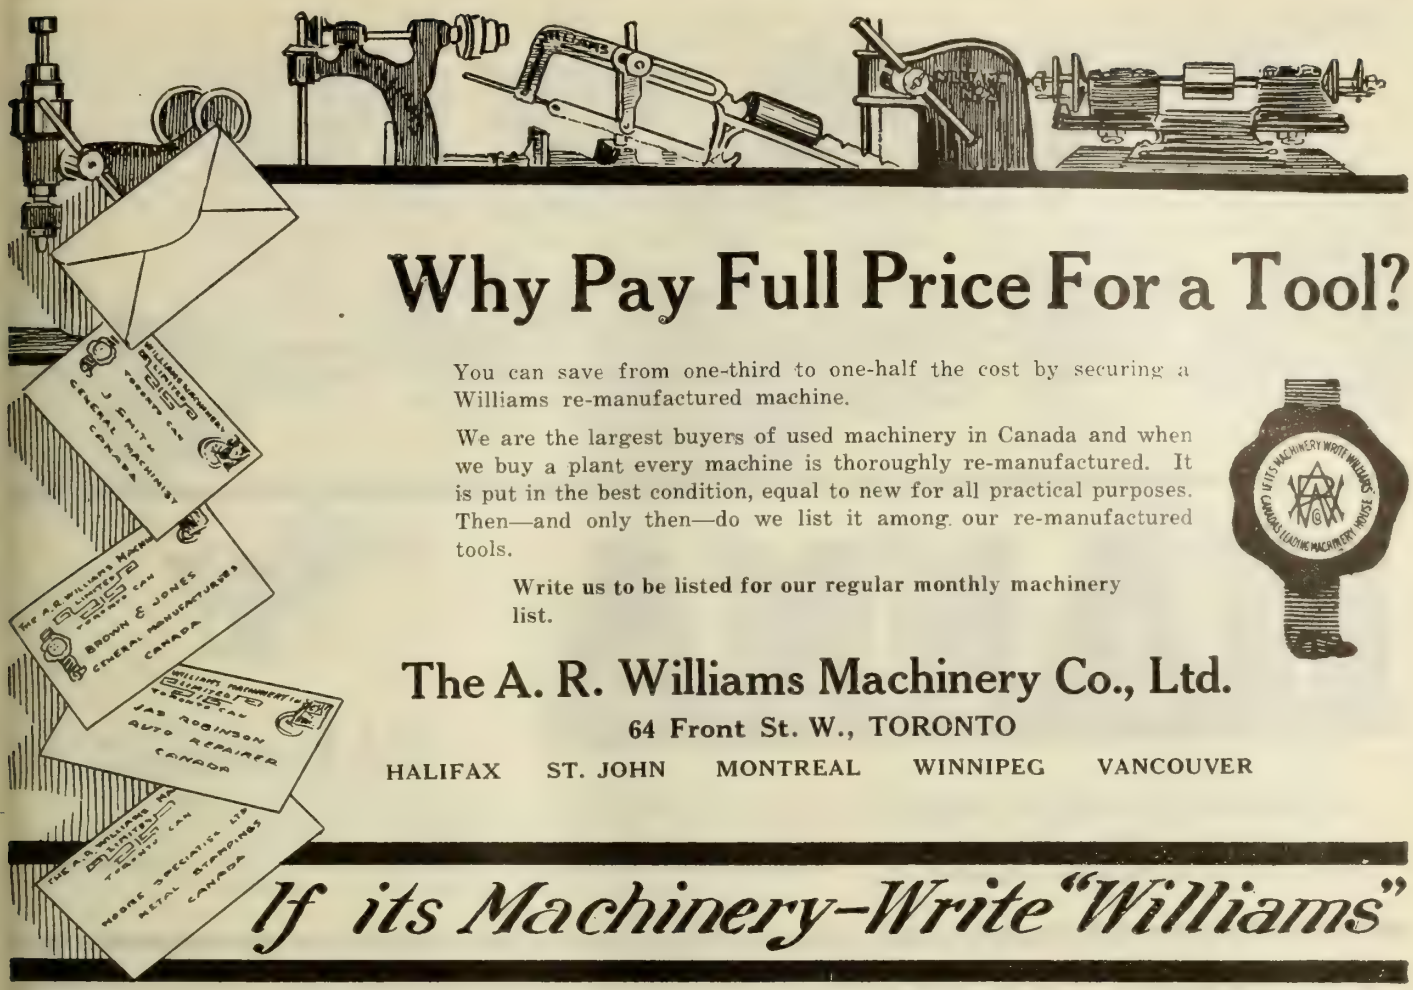
In the development of their plant at Ojibway, near Windsor, the Canadian Steel Corporation has completed a vessel slip 2,400 feet from the bank of the Detroit river. It is 202 feet wide, and dredged to a depth of 23 feet, will accommodate at the same time six of the largest lake carriers. Vessels may enter and leave the ship without tug or turning basin, as the constant current of the river makes this unnecessary. The different sections of the plant succeed each other from north to south according to the plan described some time ago. First, comes the battery of by-product coke ovens, then the coal dock, then the vessel slip and ore deck. Though docks and slip have been completed, the handling equipment is not yet installed. Two 600 ton units of the battery of blast furnaces, probably comprising fourteen units ultimately, south of the ore dock, are about completed. The open hearth furnaces are to follow, then the finishing units and auxiliary buildings. So far as plans are known production is likely to include rails, structural shapes, plates, bars, wire products, sheets, tin plate and tubes. Among the building completed are those of the general machine shop and the initial unit of the wire plant which is to be one of great proportions.

WELSH ANTHRACITE SCARCE

To indicate to what extent Americans and Canadians have been buying Welsh anthracite, states a Trade and Commerce report, a Glasgow importer told the writer, he had an inquiry from Toronto for 5,000 tons of anthracite. When he wired for quotations for early September delivery, the Cardiff firm whom he represents were unable to quote on anthracite at all, and forwarded quotations for a semi-anthracite which was the best obtainable at the moment. Canadian manufacturers will be interested in current coal prices in view of the Canadian situation. The best selected Welsh anthracite is quoted from 57s. to 62s. f.o.b. Swansea dependent upon quality, size and quantity. The ocean freight rate will total approximately 14s to Montreal which would make an average price of 74s. Montreal, which at the present rate of exchange of $4.50 would approximate $16.65 Canadian funds. As regards steam coal, prices range all the way from 20s. to 35s. dependent upon the various qualities and sizes; finest Yorkshire, which is the highest priced steam is approximately 35s., whilst ordinary steam Newcastle is nearer the lower-mentioned price.

BOOKLETS

Bearings and Bearing Metals is the title of an engineering bulletin just issued by the A. W. Cadman Manufacturing Co., Pittsburg, Pa. It contains a brief history of the development of bearing metals, covering the different types of metals and alloys used, the requirements of a bearing material, the friction in bearings and the proper lubrication of the same. This firm has likewise just issued a bulletin on Cadmar metals which comprises a digest of sixty years' pioneer work in the development of fine bearing metals. Both of these booklets are short treatises of semi-technical information on bearing metals and their uses.



Why Pay Full Price For a Tool?
You can save from one-third to one-half the cost by securing a Williams re-manufactured machine.
We are the largest buyers of used machinery in Canada and when we buy a plant every machine is thoroughly re-manufactured. It is put in the best condition, equal to new for all practical purposes. Then—and only then—do we list it among our re-manufactured tools.
Write us to be listed for our regular monthly machinery list.

NOBODY PAYS THIS BILL

SOME very interesting remarks on advertising were recently made by Sir Harold V. Mackintosh, who is described as head of the Halifax (Eng.) firm of toffee (candy) makers, and whose friends gave him a dinner in recognition of his having been made a knight. After speaking of the spirit of romance and adventure which advertising introduces into the too often dull routine of business, Sir Harold went on to say:

"Advertising is as necessary to the modern business as raw material. And the strange thing is that nobody pays the advertising bill. The bill of my own firm during the last 30 years has been something like half a million pounds for newspaper advertising alone, and our total selling costs to-day are less than they were 25 years ago. They are probably less than those of any of our competitors who may not spend a penny in advertising.

"That is a remarkable thing, but nevertheless, it is true. Nobody does pay the advertising bill if it is rightly done, but by increasing production and lessening overhead expenses and general selling costs advertising really gets thrown in. I recommend any business man who wants a hobby to do some advertising.

"I find advertising the most interesting part of my business, and I turn to it when I am 'fed up' with other things. If more business advertising were done, there would be less talk of business dullness and of getting out of it at the earliest possible moment. Advertising makes business a great game instead of a routine, and no business can succeed unless it is taken in the spirit of a game."

Sir Harold concluded by saying that every day he has surprising evidence that the public read advertisements. He mentioned a series of drawings done for his firm by a well-known comic artist. The artist's pencil had missed a stroke or two, and the consequence was that no fewer than 40 persons wrote pointing out that a lady in the picture appeared to have no arm.

CANADIAN BILLETS IN ENGLAND

There is no reason why at times, but it will only be at times, Canadian steel billets cannot come into this market, states a trade report from Birmingham. There is a steady demand, but from time to time the Germans and Belgians unload steel billets on the Birmingham market, knowing that the demand there is continuous. But as a rule, as they can obtain higher prices elsewhere, the Germans and Belgians avoid selling in the Birmingham area. However, at certain periods they are compelled to sell in this area, and then sell at a low price which knocks the bottom out of the market. This has happened quite recently and is the position to-day. At other periods, however, the price goes up after the stocks are unloaded, and then it is that Canadian steel billets might find a market. This office has arranged with an iron and steel agent in Bimingham, to notify it as soon as such an opportunity occurs. But sales of course will be governed by cables, and there will have to be immediate deliveries, for the market is a very sensitive one. At the same time, since the Germans came on the market, steel billets are selling at £6 6s. works. This it should be remembered is still £2 2s. above the German pre-war price.

An attempt has been made to sell Candian billets in the district, but the price quoted was $45—a figure quite hopeless in the present state of the market. Belgian billets figure prominently in the trade and can still be bought at under £7 per ton. The British makers show a determination to retain the semi-finished business, and have hastened to cut prices, orders being accepted at around £7 5s. for good lots—a figure at which English steel is generally preferred Higher prices are restricted chiefly to specialities, particularly to billets of the welding class for which excellent qualities are produced in this district.

CANADA A FIELD FOR ENGLISH FIRM

It is encouraging to receive further evidence that British manufacturers are seeking to extend their share of trade with Canada, from the news just to hand that the famous engineering and shipbuilding firm of John I. Thornycroft & Co., are sending a special representative from their London headquarters to tour through Canada and investigate the opportunities for their production. Thornycrofts are manufacturers of a wide range of marine and stationary oil engines, motor boats for pleasure and commercial service, motor vehicles for goods or passengers, and all types of river and ocean vessels.

Mention of the latter calls to mind the twin screw customs cruiser "Margaret" which was built for the Canadian customs by Messrs. Thornycroft's Southampton Works in 1914 for patrol service on the Atlantic coast. The firm were the pioneers of commercial motor vehicles and had the first successful vehicle running in England in 1896 which has proved the forerunner of the many thousands of Thornycroft lorries, motor omnibuses, etc., which are now running in all parts of the world, where also are to be found other productions of this British firm.

Their representative, Mr. A. Cameron, sails for Canada via New York on the White Star liner "Baltic," leaving Southampton on September 16th and on his arrival will proceed to Toronto where communications or enquiries will find him care The Bank of Montreal. He will be visiting all the principal cities of the Dominion through to Vancouver where he expects to be joined by another of the firm's representatives who is returning home after a similar mission in the Far East.

HANNA

—the name of a service for supplying pig iron to the merchant iron trade from eight separate localities strategically placed for advantageous shipping.

Cleco Pressure-Seated Air Valves

Bowes Air Hose Couplings—Cleco Never Slip Hose Clamps — Cleco Grooved Hose Nipples and Hose Clamp Tool

STYLE O.F. is an Outside Thread Female Pipe End. Made in sizes ¾-inch to 1½-inch.

STYLE I.F. is an Inside Thread Female Pipe End. Made in sizes ¼-inch to 1½-inch.

STYLE H.F. is a Female Hose End with spiral shank to insert into the hose and has groove for the Never Slip Hose Clamp. Made in sizes ¼-inch to 1½-inch.

STYLE H.M. is a Male Hose End with spiral shank to insert into the hose and has groove for the Never Slip Hose Clamp. Made in sizes ¼ inch to 1½-inch.

STYLE O.M. is an Inside Thread Male Pipe End. Made in sizes ⅜-inch to 1½-inch.

STYLE I.M. is an Inside Thread Male Pipe End. Made in sizes ¼-inch to 1½-inch.

The Male and Female Ends of Bowes Couplings interchange in sizes ¼-inch to ¾-inch. Sizes 1-inch and 1¼-inch interchange. The 1½-inch ends interchange only with themselves.

BOWES COUPLINGS

Are instantly connected or disconnected.
They are absolutely air-tight under all pressures.
They quickly pay for themselves by stopping costly leaks.
They interchange in sizes most commonly used.
They have no loose parts to be mislaid or lost.
They are made of brass and will not rust.
The U-shaped Gasket interchanges in couplings ¼-inch to ¾-inch.

CLECO AIR VALVES.

Style R.A.

Style P.O.

Style A.

Style P.O.—Made in sizes ¼ in., ⅜ in., ½ in., ¾ in., 1 in., 1¼ in., 1½ in., 1¾ in., and 2 in. Pipe Outlets. Inlets are one pipe size larger.
Style A—30° Angle Valves, are made in sizes ½ in., and ¾ in.
Style R.A.—Right Angle Valve, made in sizes ¼ in., ⅜ in., ½ in., and ¾ in.

CLECO GROOVED HOSE NIPPLES

Grooved Nipples when attached to the Hose with Wire Clamps as illustrated cannot "blow out." Wire clamp tool shown below applies the wires to hose.

The Lighting Hose Clamp Tool illustrated applies wire clamps at a cost of 1½ cents each.

In stock: Riveting and Chipping Hammers, Air Drills, Emery Grinders, Sand Rammers, etc.

Use Annealed Wire No. 14

IMPORTANT:—The Small Leaks in your "AIR LINE" mean serious loss in DOLLARS. Have you any idea of the amount of "Air" wasted in small leaks at your connections? Air Leakage through 1-16 in. opening equals 5.32 cu. ft. per minute at 80 lbs. It will pay you to install Bowes Couplings and Cleco Valves, which will stop costly leaks.

Bulletin No. 50, mailed on request.

THE MODEL HOSE LINE illustrated shows correct styles of couplings and valve to use and proper way to attach the Cleco Never Slip Hose Clamps to Bowes Couplings. No "blow-offs" can occur when "Cleco" Clamps are used.

PITTSBURGH MARKETS

(Continued from page 38)

Now, however, the appearance has been reversed. With the easier supply of steel and the unwillingness of buyers to commit themselves far ahead, it appears now that instead of the independent prices being the major part of the market, and the corporation prices the exception, as was considered the case a month ago, the corporation prices represent the real market and the independent prices merely represent delivery premiums added. Furthermore, when the premiums are generally $3 to $5 a ton and secure shipments, in most cases in from two to five weeks, it seems rather likely that the premiums will fade away altogether. Such a view is much strengthened by considering what time of year this is. If there were to be a strong market, this is the precise time when particular strength should be exhibited.

In a few weeks it will be time to begin looking forward to the usual year-end dullness. A year ago the mills could make all the steel anyone wanted, having plenty of fuel and labor. Steel ingot production rose from 11,000,000 tons a year in July, to a rate of about 25,000,000 tons at the end of October, and then slid off to considerably below 20,000,000 tons by the end of the year, simply on account of decrease in seasonal demand. The general underlying conditions, as to commercial activity, were improving right along, as was proved by the much heavier steel demand that came out after the first of the year.

Range of Prices.—In general, the range of market prices is substantially as follows: Bars, $1.90 to $2.25; shapes and plates, $2.00 to $2.25; nails, $2.60 to $2.75; sheets, $3.35 to $3.50. Merchant steel pipe is uniformly at 68 per cent., basing discount for regular mill orders, with shipment much delayed. Tin plate is $4.75, with shipment delayed only by the time it takes to make the material. Hoops and hot rolled strips are $2.75 for heavy and $3.00 for light.

Pig iron continues stagnant. Consumers apparently are unable to pay prices asked, while if they bought any considerable tonnage prices would advance further. The merchant furnaces have much more difficulty in resuming than the steel works furnaces. Possibly the situation will be relieved by some of the steel works selling pig iron. The market is quotable, more or less nominal, at $34 Bessemer, $30 for basic and $35 to $36 for foundry, valley basis.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

BLACK & DECKER BENCH DRILL STAND

BENCH DRILL STAND WITHOUT DRILL

$45.00

BLACK & DECKER SPECIAL HALF INCH DRILL

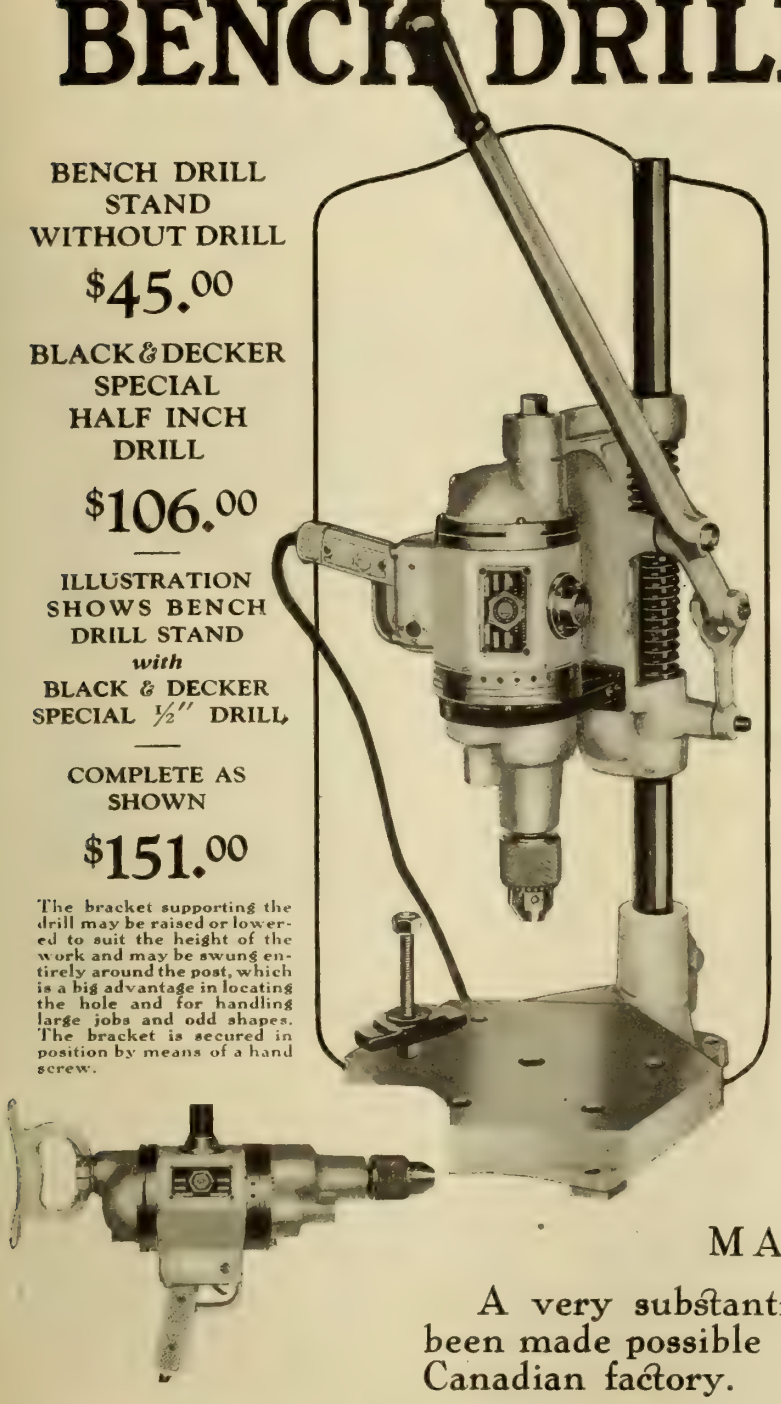
$106.00

ILLUSTRATION SHOWS BENCH DRILL STAND *with* BLACK & DECKER SPECIAL ½" DRILL,

COMPLETE AS SHOWN

$151.00

The bracket supporting the drill may be raised or lowered to suit the height of the work and may be swung entirely around the post, which is a big advantage in locating the hole and for handling large jobs and odd shapes. The bracket is secured in position by means of a hand screw.



YOU can always tell a good mechanic by his tools. He never buys inferior tools because they are cheap, if he can avoid it. But if he is a good business man as well as a good mechanic he guards against unnecessary expenditures.

In most shops a portable electric drill is absolutely indispensable and a drill press often necessary. Good mechanics everywhere are using Black & Decker Portable Electric Drills; and to make it possible for them to have the advantages of a drill press at minimum expense we have produced the Black & Decker Bench Drill Stand.

The Black & Decker Portable Electric Drill can be mounted in this stand in a few seconds and dismounted just as readily. The Stand sells for only a fraction of what it would cost to install a drill press.

The Black & Decker Post Drill Stand is similar in all respects to the Bench Drill Stand except that it has a longer column and is arranged with brackets so that it can be mounted on wall or post and the drilling table is secured on the vertical column with a hand screw so that it can be raised or lowered or swung around.

MADE IN CANADA

A very substantial reduction in prices has been made possible by the establishment of our Canadian factory.

CREDIT

BLACK & DECKER National Credit Service enables any reliable person in Canada to purchase Black & Decker equipment from his jobber on terms that permit the equipment to pay for itself.

This is the new Black & Decker Special Half Inch Drill, which has created such a sensation in the trade by reason of the fact that it combines Black & Decker quality and an exceptionally low price.

The fact that Canadian Industrials insist upon the finest tools and equipment obtainable makes BLACK & DECKER a natural choice.

Marvellous Resistance to the Action of Heat, Cold and Moisture

GUTTA PERCHA & RUBBER, LIMITED
TRADE PMS MARK
THE "RED RIBBON" BELT
TORONTO, CANADA

"P.M.S" BELTING

This remarkably efficient belting offers many convincing reasons why it should be adopted in your plant.

The troublesome effects of heat, cold and moisture, so often associated with the use of ordinary beltings, practically disappear where "P.M.S" is used. This reliable belting also offers better adhesion to the pulleys, even pliability and great strength. It delivers the maximum volume of the power which costs so much to develop. "P.M.S" will serve you faithfully —give it a trial.

The Perfect Grip

An ordinary hammer will slice the head off a nail, because it gets a grip on the head and not on the nail. With the head off, it's all off.

Williams' perfectly balanced Hammers will grip the **body** of a nail, and pull it, head and all, clear through a plank. All nails are trailers to Williams' hammers.

Heads on or heads off, for drive or pull, Williams' Superior Drop-Forged Hammers are the bosses in the nail world. Good workmen want them because they fit the hand, are perfectly balanced and are good all through.

Users of DIAMOND FIBRE and Condensite Celoron

Diamond-F

EXAMPLE NO. 1:—

A large and well-known manufacturing plant producing Cream Separators had a peculiar and expensive problem on their hands. A small steel pinion operating at very high speed persisted in giving both noise and trouble. The NOISE especially was objectionable, and many sales were lost because of this feature. They consulted us with the following result:

The gear is now made part Condensite Celoron, part steel, the noise has disappeared, and a smoother running pinion has been obtained. This is only one case where Condensite Celoron proved to be the solution of a noisy and troublesome gear drive. We have numerous other examples we can tell you about upon request.

If you have a gear problem of any nature write us full particulars and we will give you the benefit of our experience. There is no string attached to this offer and after you secure the information you are in no way obligated, although we feel sure you will come to us for material because we have the best that is made.

The complete story of both Condensite Celoron and Diamond Fibre will be mailed you on request. Both these books are worth a place in your industrial library and contain many valuable hints for shop executives and purchasing agents.

For prices, etc., write

Diamond State Fibre Company

of Canada, Limited, Toronto, Ont.

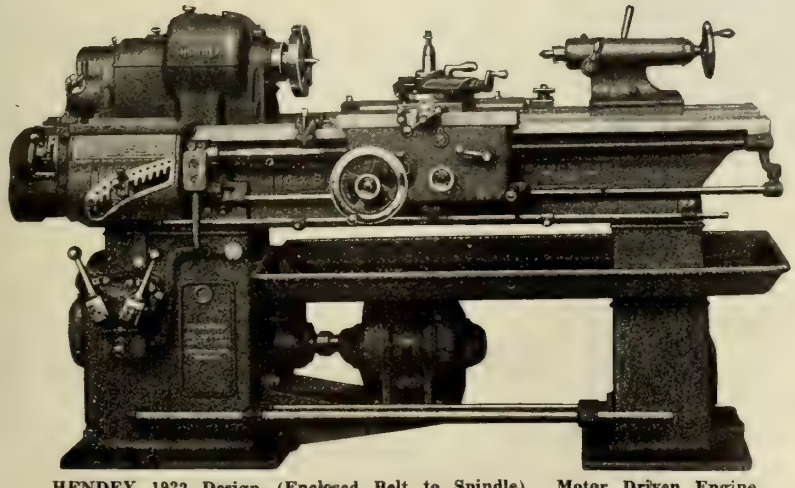
HENDEY



HENDEY 1922 Design (Enclosed Belt to Spindle). Motor Driven Engine Lathe.

The same long life, power, rigidity, ease of operation and wide working range, characteristic of all Hendey Lathes, are exemplified in this Hendey (Motor Driven) 1922 Design.

Power is applied to spindle through a wide faced belt with pull on spindle downward; this counteracts the upward thrust of tool. There are nine speed changes to belt with speed change mechanism carried in an oil tight box mounted in cabinet leg. Lathe head is back geared and gives 18 spindle speeds. Motor is constant speed and drives a reducing gear unit, which in turn transmits power to speed gear box.

The Hendey Machine Co.

"It's your Order, because your Company has a PHOTOSTAT"

"This is a job where delivery is paramount. And, in every case, I have made it a point to find out what kind of equipment the bidder had in order to make good his promise.

"Your company has a piece of equipment on which I have learned to rely. I know what the PHOTOSTAT is and what it can do. I know you will not have to lose any time tracing. You can make PHOTOSTAT copies and get started on your shop work right away. In other words you'll be days ahead and I also know that there can't be any mistakes in PHOTOSTAT copies.

"Yes, sir, you tell your chief he can thank the PHOTOSTAT for this order. I know you'll make delivery with that machine to help you."

PHOTOSTAT prints cost cents. Compare this with what it costs for a draftsman to make a tracing, a stenographer to copy a page, or an artist to reproduce a layout. The experiences of many users, written in letter form, are contained in our booklet, "A Good Word for the PHOTOSTAT."

Write for your copy to-day.

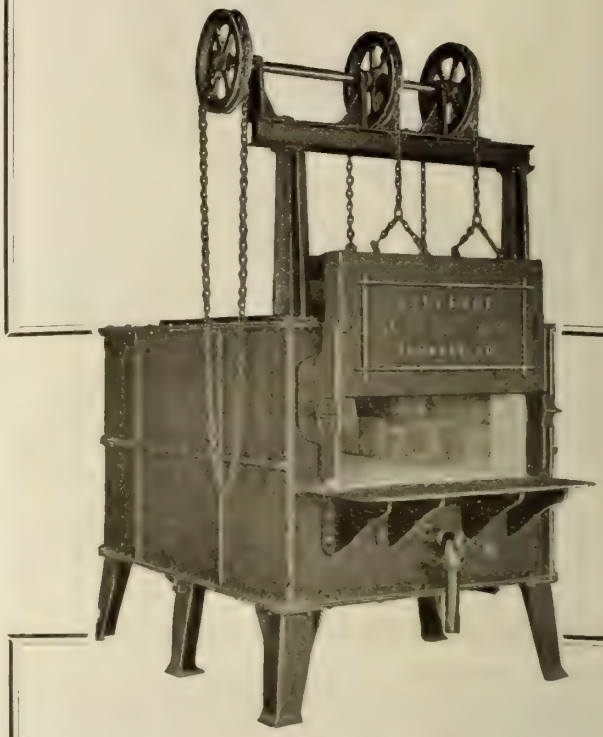
BELLEVUE
FURNACES
for every industrial use



The Solution

to your annealing and heat treating problems lies in the use of efficient economical Bellevue Furnaces.

The flame is easily controlled—attains complete combustion—heats the entire furnace quickly and uniformly—but does not come in contact with the material.

Sturdily built and reinforced, also properly lined with the highest grade heat resisting bricks—Bellevue Furnaces give excellent results.

Are you contemplating furnace installations—gas or oil burning?

We will gladly give you full information

BROWN-BOGGS

B B

Here's Just a few Features of the "B-B" Drop Hammers

As a practical man you cannot fail to appreciate the many features of the latest type of "B-B" Drop Hammers—features that combine strength, accuracy and simplicity. Here are but a few:

In place of the old-fashioned, noisy gears, these Hammers are equipped with a roller friction lift, which, because of its effectiveness in giving the closest possible approach to the full falling weight of the hammer, is acknowledged to be the most efficient in use.

The Hammer can be almost instantly stopped at any point of the down stroke by releasing the foot treadle; or, by depressing the foot treadle lightly, the hammer may be made to descend as slowly as may be desired. This is of great convenience in setting dies and gives the operator complete control of the machine at all times. It is only necessary to keep the treadle depressed if continuous blows are wanted. If the foot is removed from the treadle as soon as the blow is struck, the hammer will return to its original position, which can be at any point desired; all that is necessary to regulate the drop of the hammer is simply to set the collar on the upright shaft at the height wanted.

Our catalogues illustrating these and other "B-B" lines such as Presses, Dies, Shears, Punches, Canners' Processing Machinery, Special Machinery, etc., will prove of interest to all practical men. Write us.

THE SHEPARD ELECTRIC LIFTABOUT

You can put your load-moving and lifting on a surprisingly low cost basis

AN electric hoist for you—power lifting with its consequent economy in time and labor.

"Just the method we have long needed. We are moving and lifting our loads for less than we ever anticipated"—that's the consensus of opinion of the hundreds now using *LiftAbouts.*

A *LiftAbout* is low in first cost—made possible by standardized manufacture and quantity production. Its maintenance is negligible. Easily and quickly installed.

Incorporated in the *LiftAbout* are the same features that have made "Shepards" so well known and so widely used.

½ and 1 ton capacities for alternating or direct current.

Your first step toward low cost load-moving and lifting will be a request for our bulletin. DO IT TODAY.

"Shepard" also builds electric cranes and hoists in capacities to 30 tons.

SHEPARD ELECTRIC CRANE & HOIST CO.

"CANADIAN"
HAND POWER PUNCHES AND SHEARS

All Canadian hand power punches and Shears are made with "Armor Plate" frames.

This frame construction consists of a rolled steel plate having a tensile strength 7½ times that of cast iron. This strength permits of a machine much lighter and more compact than is possible with either cast iron or cast steel.

Let us know your punching and shearing requirements. We have an "Armor Plate" machine for the service. Remember our Armor Plate line comprises power operated machines as well as hand power.

TWO SHAFTS THAT REVOLVE AS ONE

Flexible as a Belt —
Positive as a Gear—
More Efficient than Either.

A Link-Belt Silent Chain Drive is the most positive mode of power transmission yet devised. The driving and driven shafts must revolve as one. For there is no slippage as with belts—no "play" as with gears. And there is no loss of power—no loss of time due to broken belts or gear teeth.

Chain your power to your driven machine. It's the most economical, positive and efficient method of power transmission. Our 128 page data book No. 125 tells why. Send for a copy. Ask our engineers to help you solve your power transmission problems.
